It must be emphasized that this study is merely in its preliminary stages, as only a limited number of cases have been treated. Nevertheless the results obtained so far have been promising, and suggest that further work is desirable. The method was evolved in an attempt to solve the difficulties experienced in the treatment of burns of the hands and face and of those of third degree: most of the burns treated have been of the second degree, the type usually encountered in civil life. We have not had an opportunity of treating the many burns of the third degree met with in Service casualties. There is no suggestion that in extensive burns euglamide should be used as an alternative to tannic acid; it is well recognized that in such cases the application of a coagulating agent is essential to combat secondary shock. There are certain types of burns, however, in which euglamide treatment offers (so far as we can judge from our present experience) definite advantages as compared with other methods. This applies more especially to those lesions in the treatment of which the coagulating method has been adversely criticized; thus it is well known that all third-degree burns become infected, while second-degree burns in certain localities—e.g., hands and face—may show undesirable after-effects when treated with tannic acid. For these reasons the saline-bath method has recently been revived, but it would appear to have certain drawbacks. It involves considerable nursing attention and the employment of elaborate facilities; this in itself would make it very difficult to deal with more than a limited number of cases at any particular time. Moreover, the method does not control sepsis, though this could be done by the addition of albucid soluble to the irrigating fluid. In this connexion it is of interest to note that Carrel and his co-workers showed that the rate of healing of wounds is appreciably increased by the addition of certain antiseptics to the irrigating fluid (Carrel and Dehelly, 1918).

The euglamide method does not appear to possess the disadvantages associated with the tannic acid and saline techniques of treatment. It has proved effective in dealing with burns of the face and hands, allowing of rapid and uneventful recovery. Indeed, in two cases in which an accurate comparison with tannic acid was possible the rate of recovery with euglamide was very gratifying. This may have been due to the fact that, with euglamide, movement of the fingers was possible from the first and oedema was rapidly controlled.

In third-degree burns the results obtained in Case 7 would suggest that the paste allows of an early separation of slough, control of sepsis, and the development of healthy granulating surface for early skin-grafting.

Routine bacteriological examinations have been and are being made in all cases with a view to determining the possible effect of the paste on different types of infecting organisms. With the limited series of cases so far studied a discussion of the results would be premature. At the same time it is of interest to note that investigations performed by Dr. de Waal in the department of bacteriology of the University of Edinburgh have shown by means of *in vitro* experiments that albucid soluble exerts a bactericidal and bacteriostatic action against *Str. pyogenes* and also some bacteriostatic action against *B. coli*. (We are very grateful to Dr. de Waal for allowing us to quote these as yet unpublished results.)

It is possible that soluble sulphonamides other than albucid might be more suitable for the treatment of certain types of infected burns, and in our further work we hope to study the possible value of euglamide pastes containing these.

Summary

Euglamide paste has proved very useful in the treatment of burns in certain areas—e.g., hands, face, scalp, feet, abdomen, buttocks, scrotum, and penis.

In small second-degree burns the paste caused slight pain on application in a few cases; later on it is soothing, non-irritant, and healing. Preliminary cleansing can often be carried out without anaesthesia. The paste is simple to apply, and the patient has more freedom of movement than when a coagulating agent is used

Infected burns have also responded in a very satisfactory manner to treatment with the paste.

In one purely third-degree burn treated with euglamide a clean surface suitable for grafting was rapidly obtained.

Only a limited number of cases have so far been investigated; but in our opinion the results have been promising enough to justify further work.

We should like to express our gratitude to Profs. A. J. Clark and J. R. Learmonth for their constant interest and advice in this work.

We are greatly indebted to Mr. Edwards, of Schering Ltd., for the supply of the albucid soluble used in this work.

DIGESTIVE DISORDERS IN THE FORCES

BY

J. GIBSON GRAHAM, M.D., F.R.F.P.S.G.
Lieut.-Colonel, R.A.M.C.; Officer in Charge of the Medical Division of a Military Hospital

AND

J. D. OLAV KERR, M.B.
Captain, R.A.M.C., graded Physician

The types of cases seen in the wards and out-patient departments of military hospitals present general variations similar to those found in civil hospitals. Thus rheumatic and respiratory disorders have the usual seasonal fluctuations. On the other hand, conditions such as effort syndrome and general psychological disorders tend to increase temporarily with the periodic intake of recruits. But in our experience in a home hospital during the present war the only cases showing steady addition in numbers comparable to the increasing size of the Army have been those with digestive disorders, and in consequence we have been struck by their significance in the Forces. Our cases have been drawn from all branches—Navy, Army, Air Force, and Women's Auxiliary Services. However, Army patients have constituted an overwhelming majority. It was noted, over a period of fourteen months in a military hospital in a north-western area, that of 790 medical in-patients 246 (31.1%) were admitted on account of gastro-intestinal complaints; while in a north-eastern hospital it was found that of 980 medical admissions 353 (36%) were gastro-intestinal cases; but it must be borne in mind that these hospitals are used largely for the investigation of such cases, which are especially sent for this purpose, and consequently the percentage of gastro-intestinal conditions admitted is not a measure of their incidence in all hospitals. Nevertheless, gastric disorders are an important problem in the Services.

Methods of Investigation and Treatment

In a large north-western military hospital our procedure in assessing cases of gastro-intestinal disorder is to obtain an accurate case history, make a detailed clinical examination, and then undertake certain lines of special investigation. In what we may term the "gastric" group, which includes cases of gastritis in addition to those of peptic ulcer, tests for occult blood in the stool are performed after seventy-two to ninety-six hours on a haemoglobin and chlorophyll-free diet. This is followed in many instances by a fractional test meal. Finally an *x*-ray examination by barium meal is carried out in all save a very few cases concerning which positive findings are readily obtainable from recent investigation in civil life. Where the gall-bladder or large bowel appears to be implicated cholecystography or examination by barium enema is carried out.

With the gastric group the dietetic treatment as outlined by Hurst (1931) is employed with excellent results. By this method the modern dietetic principles in treating peptic ulcer are followed—that is, physical rest is combined with a well-balanced diet of an adequate caloric value and vitamin content.

Table I shows the proportions of major types of digestive disorder admitted to this military hospital, and their age incidence. At once it is seen that cases of peptic ulcer form the chief problem among the dyspepsias, accounting for actually 64.23% of such patients. No attempt has been made to study the incidence of dyspepsia in the various branches of the Forces or to examine sex incidence, since this would be of no value with the figures at our disposal. It was found that there were four main groups of digestive disorder: duodenal ulcer (54.88%), gastric ulcer (9.35%), gastritis (24.39%), and miscellaneous dyspepsias (11.38%). In this last group psychological disorders appeared to play a relatively unimportant part, and we were struck by the rarity of malingering. In our series there were no fatalities.

TABLE I.—*Age Incidence in Major Dyspepsias*

	Under 20	20–29	30–39	40–49	50+	Total Cases
Duodenal ulcer ..	3	52	49	27	4	135
Gastric ulcer, including one stomal ulcer	—	5	10	7	1	23
Gastritis	1	22	19	13	5	60

By the addition of 28 cases of miscellaneous dyspepsias a total is reached of 246 consecutive admissions on account of digestive disorders. There were 790 medical admissions in all during the fourteen-months period under review.

Duodenal Ulcer

Duodenal ulcer formed 85.5% of the cases of peptic ulcer—14 were in officers, the remainder in other ranks. There were no female cases. Perforation had occurred in civil life in 4 instances and in a fifth shortly after embodiment. In 8 patients gastro-enterostomy had been performed, and in 18 appendicectomy. There was a history of either haematemesis or melaena, or both, in 5 patients previously and in a similar number after entering the Forces. The average duration of symptoms was seven years, and only 5 patients (3.7% of the total cases of duodenal ulcer) stated that indigestion occurred first after embodiment. The stool was found to be positive for occult blood in 80% of cases. Fractional test meals were carried out in many instances (Table II). The results are in keeping with those usually found—namely, the majority of such cases show a well-marked hyperchlorhydria.

TABLE II.—*Test-meal Findings*

	Achlorhydria	Hypochlorhydria	Normal	Hyperchlorhydria	Total Cases
Duodenal ulcer ..	—	2	20	26	48
Gastric ulcer ..	1	3	3	1	8
Gastritis	11	15	17	12	55
Miscellaneous ..	1	4	6	1	12

A barium-meal examination was carried out and an ulcer niche or distortion of the duodenum was noted in all but one case, in which, although the *x*-ray findings were negative, an acute ulcer was diagnosed. (In this man an active ulcer had been noted at a previous examination in 1937; the stool was strongly positive for occult blood, and in addition a marked hyperchlorhydria was present.) Our well-marked positive findings can be explained on the fact noted above—that the average duration of symptoms in our series was seven years. Moreover, in over 96% of the cases exacerbation of a chronic ulcer was dealt with. Recrudescence of symptoms occurred rapidly after enlistment—in 70% within two months and in the remainder within eight months.

Gastric Ulcer

The cases of gastric ulcer numbered 23—14.6% of the peptic ulcer total. Fifteen had lesser-curvature ulcers, the remainder were prepyloric. There were 2 officers but no female cases. Two perforations occurred in this

group—1 before the war and 1 after. There was a history of haematemesis in 3 patients before enlistment, with recurrence in one instance two months after embodiment. In one man included in this group gastro-enterostomy had been performed on account of duodenal ulceration with subsequent development of a stomal ulcer. Appendicectomy had been previously undertaken in 2 patients.

With the exception of 4 patients (17.4%) there was a history of digestive trouble in civil life, the average duration of symptoms being five and a half years. The situation of the ulcer did not affect this last point. The stool was found to be positive for occult blood in 66% of the cases. The results obtained from fractional test meals, while too few to draw any general conclusion, show a rather lower acidity than in the duodenal group. This is explained by the greater irritation of the gastric ulcer, resulting in concomitant gastritis and consequent over-production of mucus (Hurst, 1935). A barium meal showed an ulcer niche in all but two instances. This examination was carried out within ten to fourteen days of admission to hospital, since it was of the highest importance to obtain radiological evidence of the presence of ulcer for purposes of the consequent medical boards. As has been noted by several observers (Hurst and Stewart, 1929; Hurst and Ryle, 1937), the ulcer niche in the gastric mucosa may with adequate treatment cease to be seen after three to four weeks. As with the cases of duodenal ulcer, relapse after embodiment occurred within periods varying from a few days to two months in the bulk of cases, but a few of these patients had remained well for periods up to seven months after enlistment.

Disposal of Cases of Peptic Ulcer

Where investigation had revealed the definite presence of peptic ulceration every patient was brought before a medical board. Apart from officers all these patients were found to be unfit for any form of military service with the exception of one man suffering from gastric ulcer who was passed as fit for home service only. Commissioned ranks, for reasons to be stated later, were dealt with differently. Of 14 officers with duodenal ulcers 5 were passed as fit for home service only, the others being returned to civil life. One of the 2 officers with gastric ulceration was graded as fit for home service only; the other was passed fit for general service.

In the last case there were symptoms of indigestion for some four months with loss of weight. This patient was admitted to another hospital, where laparotomy was performed. A mass noted as "either malignant or inflammatory" was observed in the posterior pyloric region, extending into the duodenum. Gastro-enterostomy was performed and the abdomen closed. He came under our care about four months afterwards, in excellent health, gaining in weight and symptomless. The stool was negative for occult blood. A fractional test meal gave normal findings, and on two occasions the barium-meal examination showed a normally filled stomach and a functioning stoma. The Kahn test was negative.

Gastritis

Sixty patients—almost 25% of the cases of dyspepsia and therefore an important moiety—were diagnosed as suffering from gastritis. Many of them gave a history of pain and vomiting after food that was so typical of peptic ulcer that the results of barium meals and fractional gastric analyses formed essential parts of the diagnostic criteria. We have adhered to the views of Hurst (1935) in assessing these cases, and the test-meal findings in Table II show that great variations in acidity occur in such conditions. Abundant mucus was present, especially in the fasting juice. The great majority (79%) suffered from exacerbation of a chronic gastritis, there being a history of indigestion of several years' duration (average seven years). The remainder gave no history of gastric trouble in civil life and were examples of acute gastritis due to alteration in diet following embodiment. There were four cases in commissioned ranks: the others occurred among N.C.O.s and men, with the addition of one in a member of the A.T.S.—our only female case. Thirty-one complained of symptoms arising rapidly after embodiment, and the remainder were able to carry on for periods up to one year. A weak positive result for faecal occult blood was obtained in 25% of all cases of gastritis.

Disposal of Patients with Gastritis

All save two patients in this series did well and were returned to their units, in some instances via a convalescent home. It was explained to these men that they did not suffer from any serious digestive ailment, such as a ulcer, and they were instructed to avoid particular "heavy" constituents in their Army diet. In one instance a man aged 49 was returned to civil life owing to absence of improvement (he had achlorhydria); a second was dealt with similarly on account of a concomitant hand injury which interfered with his duties and superadded a psychological element.

Miscellaneous Group

A *miscellaneous assortment of gastro-intestinal trouble* accounted for the remaining cases of dyspepsia and comprised only 11.38% (28 cases). They were made up as follows; abdominal adhesions, 6 cases; catarrhal jaundice, 5; chronic cholecystitis, 2; cirrhosis of liver, 1; duodenal diverticulum, 1; gastric carcinoma, 1; gastro-enteritis, 5; mucous colitis–spastic colon group, 6; and *one example of gastro-intestinal supersensitiveness.* In this series 4 cases were in females. Seven of these patients were returned to civil life, while 2 were found fit for home service only. The large proportion of these cases "boarded" out of the Army is not of real significance owing to the small total number involved.

The patient showing gastro-intestinal supersensitiveness is of interest. A gunner aged 44 was admitted with a history of haematemesis. He stated that he had seldom suffered from gastric symptoms in civil life, but since embodiment had been frequently seized with severe abdominal pain accompanied by vomiting. He blamed the midday meal. On admission, although the stool contained occult blood, he stated that he felt perfectly well and wished to return to his unit. A fractional test meal gave normal findings and a barium-meal examination did not reveal evidence of either gastric or duodenal ulcer. The stool was tested after another seven days and was negative. At this point he was placed on Hurst's diet for peptic ulcer, Stage 2, and on irregular occasions complained of severe epigastric pain and vomited after meals. It was suspected that in this instance we were dealing with an example of supersensitiveness to a particular food, and the offending article—carrot—was detected and eliminated from his meals, with rapid and complete cure. He then stated that he had always avoided this vegetable at home because he did not like it.

Summary of a Review of Digestive Disorders Seen in a North-Eastern Military Hospital

During the period April to October, 1940, it was found that of 980 medical cases in a north-eastern hospital 353 (36%) were admitted for radiological investigation on account of digestive complaints. In just over half the *x*-ray findings were negative. The majority of patients in this radiologically negative group suffered from gastritis, but 22% showed an anxiety neurosis of some form or another. Where there were positive *x*-ray findings duodenal ulcers were found to be nine times as common as gastric. Of the cases proved to

have ulcer 21 gave a history of operation for perforation: 23 had undergone gastro-enterostomy, and 21 gave a history of haematemesis (i.e., 15.8% of cases of proved ulcer). Of the 353 cases under review 56 had previously undergone appendicectomy. Of the cases examined by barium meals 54% were found unfit for further military service by medical boards. The mortality in the whole series was *nil*. Accordingly these results are *in substantial agreement* with those in the north-western hospital.

Discussion

The miscellaneous group of gastro-intestinal troubles, which make up only 11.38% of our series, consisting of hepatic and colonic disturbances, tumours, etc., have already been described. Nothing more need be written about them as the purpose of this paper is to draw attention to the problem presented by dyspepsia due to ulceration or gastritis.

There seems little doubt that digestive disturbances, particularly those due to peptic ulcer, have increased enormously during the past twenty years. This has been noted with concern in other countries, notably in the United States (Hinton, 1933; Wolfert, 1937; Rivers and Ferreira, 1938). The magnitude and importance of the increasing incidence of peptic ulcer have been brought sharply to the notice of the medical profession during the present war, and that condition has been shown to be the major cause of sickness among our Forces. Willcox (1940) found that in a British convoy from France which contained 174 medical sick 23.5% suffered from the dyspepsias. This group after investigation revealed the unexpected incidence of approximately 66% of peptic ulcer. Again, Morris (1940) noted that of 500 officers and men suffering from dyspepsia and examined radiologically in a military hospital 45% suffered from either duodenal or gastric ulcer, or both. Recently Payne and Newman (1940) carried out an important investigation into the subject of dyspepsia in the Army and found that, out of 287 cases, peptic ulcer was proved in 226 (78.7%), and to this they added a further 21 cases (7.3%) with probable ulcer. No significant difference was found on separating these cases into groups from the United Kingdom and France.

In our own series of 246 cases with gastro-intestinal complaints peptic ulcer was present in 64.23%, while cases of duodenal ulcer made up 85.5% of the latter. This significant fact was also noted by the authors quoted above. These patients, whether they suffered from duodenal or gastric ulcer, almost without exception were in the habit of carrying out a dietetic regime in civil life which approximated to the post-ulcer regime used at the present day, and with success so long as they adhered to it. This is a striking tribute to the efficacy of the medical treatment of peptic ulcer, since we find large numbers of patients pursuing their vocation efficiently and with little interruption. In this connexion it was pointed out by Colonel H. Letheby Tidy in his Harveian Oration (1936) that gastric ulcer is a more serious condition than duodenal ulcer, but he concluded that the outlook as regards complete cure was unfavourable in both.

The majority of those whose breakdown did not occur until some months after embodiment belonged to older age groups or found it possible to obtain suitable food. Such patients often stated that they purchased meals at the local canteen, especially the midday meal, trying to avoid stews, which they dreaded. Moreover, they were able to treat themselves with alkaline powders, usually of some much-advertised brand. Similarly, since a suitable diet was a less serious problem, commissioned ranks were sometimes able to carry on for periods up to a year before exacerbation of symptoms occurred. Officers could often carry on in comfort in France until active hostilities precluded suitable diet. In this connexion the severe physical strain and irregular meals before evacuation undoubtedly had an adverse effect. This was also noted in patients after the Norwegian campaign.

A feature in our cases is the general absence of severe complications. Thus in the duodenal ulcer group (135 patients) we find only one case of perforation, and only 5 cases (3.7%) of haematemesis occurring while serving with the Forces. During the period under review our surgical colleague Lieut.-Colonel E. G. Gerstenberg admitted 2 cases of perforation; in both a chronic ulcer of the anterior duodenal wall was found. In our gastric ulcer group there was but one instance of perforation after embodiment and one of haematemesis. On the other hand, Hurst and Ryle (1937) have stated that some 30% of ulcer patients in private practice show bleeding at one time or another. Graham, Alexander, and Kerr (1939) found over a ten-year period that approximately 57% of the cases of peptic ulcer in a civil hospital were admitted on account of active bleeding. Such marked discrepancy is probably accounted for by two factors: first, men with ulcer which is showing evidence of activity are unlikely to be passed as fit by the civil recruiting boards; and, secondly, sufferers go sick and receive treatment earlier in the Army than in civil life. The high proportion of ulcer cases with occult blood present in the stool suggests that, but for the discovery of this, gross bleeding might have become an important problem.

We were unable to obtain any convincing evidence of serious avitaminosis, nor was dental sepsis a more prominent feature in such cases than in other medical admissions.

In civil life many of these patients led a regular existence suited to their trouble. They seldom admitted that heavy smoking or alcohol played any part in their breakdown; indeed, we were struck by the number who stated that they were teetotal and never smoked more than ten cigarettes daily. Embodiment brought these men new problems—worry and the adjustment and strain of taking up a fresh mode of life and leaving their family or business. Altered conditions of living, lack of sleep, unsuitable billets, all affect such subjects adversely. Lastly, the Army diet is not suitable for persons who show the ulcer diathesis. The official decision to discharge men with active ulcers or with a history of long-standing severe gastric illness is of proved wisdom under the conditions of modern warfare.

Patients suffering from exacerbation of chronic gastritis, although they ascribed some improvement in their condition in civil life to the avoidance of fried food, stews, and pastries, did not as a class receive the same amount of benefit from a dietetic regime and were more introspective. As was found in the cases of peptic ulcer, and for similar reasons, the group who broke down several months after embodiment consisted mainly of the older men. It has been noted already that only 2 of the 60 patients in our series required to be discharged from the Service.

All cases of acute gastritis without previous history made a rapid recovery and the men returned to their units well. The cases of this type actually admitted to hospital are of course few, since the regimental medical officer is able in the vast majority of instances to deal with them himself. Thus it is seen, almost without exception, that men with gastritis, both chronic and recent, when given a fresh start and some general dietetic principles to go on, can safely be allowed to remain in the Army without alteration in category.

The high incidence of digestive disorders, particularly of duodenal ulcers, seen in the past two decades has been

thrown into sharp relief by the mobilization of our manpower for war. It would occasion little surprise if the quickening tempo of modern life were found to have a direct bearing on the problem presented by the increasing occurrence of the dyspepsias. No entirely convincing clue to this enigma has yet been offered, but it will be interesting to learn whether or not life in our Forces is adding significantly to the already high frequency of such disorders. Final judgment on this point must, of course, await the conclusion of the present conflict. We are in entire agreement with the leading article in the *British Medical Journal* of December 14, 1940, which stated that "the Army still marches on its stomach even though it travels in mechanized vehicles," and the dyspeptic passenger must be carefully scrutinized before taking part in the journey.

Summary and Conclusions

In Army medicine digestive disorders are presenting a large and increasing problem. Of 790 medical in-patients 246 (31.1%) were admitted to a military hospital on account of gastro-intestinal complaints.

The methods of investigation and treatment of dyspeptic patients in a large military hospital are outlined.

Of 246 cases of digestive disorder 135 (54.88%) were found to have duodenal ulcers, 23 (9.35%) had gastric ulcers, 60 (24.39%) gastritis, and 28 (11.30%) miscellaneous dyspepsias. Details are given of the clinical findings in these groups and of the ultimate disposal of the patients. A review of 353 similar cases admitted for radiological investigation to another military hospital yielded substantially similar results.

Many observers have shown that peptic ulcer is the major cause of sickness among the Forces. In our series 64.23% were proved to have peptic ulcer, cases with duodenal ulcers forming 85.4% of this group.

Complications such as haematemesis and perforation were conspicuous by their rarity.

In the vast majority of ulcer patients we were dealing with an exacerbation of an old-standing condition which was adequately dealt with in civil life by simple medical treatment, enabling the sufferer to continue as a useful member of the community. But the strain of Army life tends to induce recrudescence.

Patients with acute gastritis can often be adequately treated by their own medical officers, while men with either acute or chronic gastritis, if given a fresh start by a period of residence in hospital, generally do well and can safely be allowed to remain in the Army.

It is suggested that the quickening tempo of modern life is related to the increasing occurrence of the dyspepsias, especially peptic ulceration, and the question is raised whether or not Army life will add to the frequency of such disorders.

The point of highest military importance which emerges from this investigation is the large proportion of those with a definite history of peptic ulcer who on embodiment in the Army soon become a serious charge on the medical authorities.

Our grateful thanks are due to Colonel H. Letheby Tidy, also to Prof. C. H. Browning, for helpful advice and criticism; and to Colonel D. F. Mackenzie, D.S.O., A.M.S., Colonel R. A. Lennie, T.D., A.M.S., and Lieut.-Colonel A. M. Simson, R.A.M.C., for permission to carry out this work. We also wish to express our gratitude to the pathological and radiological staffs concerned and to those who have so loyally co-operated in the ward work.

EXPERIENCES WITH SULPHANILAMIDE DERIVATIVES IN SOME TROPICAL CONDITIONS

BY

K. VIGORS EARLE, M.D., B.Ch.

Second Government Medical Officer, Administration of Nauru, Central Pacific; late Medical Officer, United British Oilfields of Trinidad, Ltd.

A review by Buttle (1939) of the uses of sulphanilamide derivatives in tropical diseases prompts me to give my experiences with this drug not only in some purely tropical diseases, but also in some of world-wide distribution the clinical picture of which is influenced by the tropical background, and in the treatment of ordinary streptococcal invaders of pathological conditions essentially tropical in origin.

All the cases reviewed were treated in Trinidad, British West Indies, except where otherwise stated. The drugs used were sulphapyridine (M & B 693) and sulphanilamide (prontylin).

Diseases due to Filterable Viruses

(*a*) *Dengue.*—In a series of cases studied during an epidemic in Trinidad (Earle, 1939a) sulphapyridine had no apparent curative effect on the temperature, rash, or cervical gland enlargement (which is present in from 30 to 60% of cases—Castellani, 1939), arthralgia and myalgia, or state of malaise in the patient. Indeed, the epigastric pain and headache produced by the drug so exacerbated the patient's condition that its use had often to be abandoned. The danger of reducing the leucocytes in a condition in which there is already a leucopenia is a further disadvantage in the use of sulphapyridine.

Case 1.—A female English child aged 2, first seen on April 26, 1939, when she complained of generalized pain. Temperature 101° F.; a well-marked dengue rash was present. Sulphapyridine, 0.125 gramme (1/4 tablet) four-hourly, was given. An improvement was recorded on April 27, the temperature falling to 99° F.; but it subsequently rose again, giving the saddle-back type of curve (Megaw, 1937). Recovery was uninterrupted. Here, although at first sight it might be thought that the drug had had a curative effect, it was obvious that it had no influence on the course of the disease.

Case 2.—A female aged 17, English, seen on February 2, 1939, during the dengue epidemic, when she had generalized body pain, headache, and enlargement of the submaxillary and superficial cervical lymphatics. Temperature 103.8° F., pulse rate 126. A red flush over chest and face was seen. Sulphanilamide 2 grammes (4 tablets) was given at once, followed by 1 gramme four-hourly. The course was continued for five days. No alteration in the patient's condition occurred, and she took the usual time to recover.

Case 3.—A Scotsman aged 35, seen on February 12, 1939, when the usual clinical signs of dengue were apparent. 1 gramme of sulphapyridine was given four-hourly. The next day the pains had greatly increased and epigastric pain, nausea, and vomiting were present. The drug was suspended; the patient's condition improved after twenty-four hours, and he made an uninterrupted recovery.

(*b*) *Lymphopathia Venereum.*—The beneficial effects of sulphanilamide compounds in my practice have already been described (Earle, 1939b, 1939c, 1939d). Briefly, good results may be expected in early cases, before fistula formation. But even in later stages or when fistulae have formed some improvement may result. Lymphogranulomatous papillae of the vulva and rectum are reduced in size and indurated strictures of the rectum become softer and therefore amenable to dilatation.

MEDICAL EVANS PRODUCTS

The Topical Application of Sulphanilamide

STREPTOCIDE OINTMENT

Research at The Evans Biological Institute has resulted in the issue of Streptocide in solution as an ointment. The solvent used is non-toxic and the ointment may be applied over extensive areas. Streptocide Ointment contains 5 per cent. of Streptocide. There are numerous infective conditions of the skin in which its use is indicated. Favourable reports have been received concerning the following :—

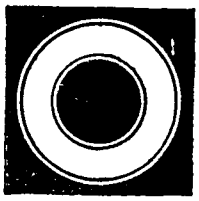
Cellulitis	Impetigo
Chronic Ulceration	Infected Wounds
Cytolysis	Post-Scarlatinal Rhinitis
Eczema	Scarlatinal Rashes
Empyematous Sinus	Varicose Ulcers
Erysipelas	Whitlow

Issued in 2-oz. Containers .. .. 2/6 each
„ „ 1-lb. „ .. .. 14/6 „

STREPTOCIDE CREAM

Streptocide is also issued in the form of a non-greasy cream, which is specially recommended in acute inflammatory conditions when rapid absorption of the drug is desired.

Issued in 2-oz. Containers .. .. 2/9 each
„ „ 13-oz. „ .. .. 14/6 „



Prices, Technical Literature and Samples will be sent on application to Home Medical Department, Hanover Street, Liverpool

Ulcerative Granuloma

The action of sulphanilamide alone on ulcerative granuloma, although favourably reported on by Ross (1939), has in my experience proved unsatisfactory. When combined with injections of fouadin (a complex salt of trivalent antimony with a pyrocatechin derivative) the results are much more encouraging (Earle, 1940–1). The treatment consists of a course of sulphapyridine, 3 grammes daily for five days, the course being repeated after an interval of three to four days. At the same time the standard course of fouadin, injected intramuscularly, is given. (Initial dose 1.5 c.cm., rising to 5 c.cm.; total dosage, 75 c.cm.) The injections are made every second day.

Tropical Pyomyositis

The action of sulphanilamide in this condition has already been described (Earle, 1939e). The standard dosage of the drug may be given, and good results are to be expected.

Tropical Ulcer

(*a*) *Typical Tropical Ulcer.*—Sulphanilamide is of value only in very early ulcers or pre-ulcerative papules of the idiopathic type (Earle, 1940a). It is of very limited value in old-standing ulcers.

(*b*) *Tropical Ulcer Associated with Popliteal Abscess.*—I group separately the case described below, as I have only once seen tropical ulcer associated with popliteal abscess in all the cases of this ulcer I have studied in Trinidad. This type of case is common among Chinese coolies at Ocean Island (Central Pacific) and among native Nauruans at Nauru. Possibly this form of tropical ulcer differs from the ordinary tropical ulcer in aetiology.

Case 4.—A male negro aged 14, first seen on June 22, 1939, when examination showed a tropical ulcer of the left foot associated with a popliteal abscess of the same side. Sulphapyridine, 2 grammes daily for five days, was given. On June 30 the popliteal abscess was almost healed: the course of sulphapyridine was repeated, and on July 11 both abscess and ulcer had healed. (Cod-liver oil was used as a local application in this case.)

Streptococcal Infection Implanted on to Fungous Diseases

In the Tropics certain fungous diseases appear to be readily infected by streptococci.

(*a*) *Intertriginous Ringworm.*—The infection caused by *Trichophyton* (*Epidermophyton*) *interdigitale* often leads to severe cellulitis or severe ulceration or maceration of the feet, due to a secondary streptococcal infection. I have found it advantageous to clear up the secondary infection with sulphanilamide before proceeding to a radical cure of the fungous condition.

Case 5.—A Chinese clerk aged 30, first seen on January 10, 1939, when he complained of pain and swelling of the left foot. On examination there was a well-marked ringworm of all the interdigital clefts, with cellulitis involving the whole foot. Sulphapyridine, 3 grammes daily for six days, was given, and magnesium sulphate and glycerin were applied to the open lesions. On January 19 the cellulitis had cleared up, and local treatment (Castellani's fuchsin paint) could be started.

Case 6.—An English storekeeper aged 40, seen on December 3, 1939, when he complained of severe ulceration of the interdigital clefts and soles of both feet, this condition supervening on "athlete's foot." Sulphapyridine, 4 grammes daily for four days, was given. The course was repeated twice, two-day intervals separating the courses. At the end of these courses the secondary infection had healed sufficiently for the fungous condition to be treated by x-ray therapy.

(*b*) *Fungous Infection of the External Ear.*—"Tropical ear," or "salt-water ear," appears to be an invasion of the external auditory meatus by the Pityrosporon of Malassez, secondarily invaded by streptococci and staphylococci. If untreated, crops of painful furuncles may occur. I found it a useful precaution to give sulphanilamide in incipient "tropical ear" and also in later cases in which furuncles had already formed. In five cases, all in young children, sulphapyridine given in an appropriate dose at the first sign of soreness following sea-bathing prevented the onset of complications. In a sixth case multiple small abscesses supervening in an infected ear were cured in three days.

Complications of Yaws

One case of severe secondarily infected yaws favourably influenced by sulphapyridine is worthy of record.

Case 7.—A negro boy aged 3, found on May 23, 1939, to be suffering from infected and ulcerative yaws of legs. Sulphapyridine, 1 gramme daily for three days, together with bismuth injection, was given. On June 1 the gross secondary infection had cleared up. Bismuth injections were continued and neosalvarsan injections were added to the treatment.

Lymphangitis

(*a*) *Non-filarial.*—Lymphangitis of obscure origin is seen in Trinidad. It is not necessarily filarial, since filaria is rare in that island (see Health Reports of Trinidad and Tobago for the years 1937 and 1938). A typical example of non-filarial lymphangitis is appended.

Case 8.—A white Trinidadian overseer aged 48, seen on March 15, 1940, when he complained of fever, and pain and swelling of the right leg. He gave a history of a shrapnel wound in the right thigh during the 1914–18 war. Since his demobilization and return to Trinidad he had had recurring attacks of lymphangitis in the affected extremity, these being at times combined with erysipelas-like attacks. The temperature was 102° F., pulse rate 96. The right thigh and calf were swollen and painful. Irregular red areas, somewhat like erysipelas patches, were scattered over the skin of the calf. Thickened, red, inflamed lymphatics were seen in the thigh, and the crural lymph glands were swollen and tender. About four inches distal to Poupart's ligament there was a deep irregular scar, which caused great distortion of the adjacent tissues. The whole extremity was extremely tender. *Plasmodium vivax* but no microfilariae were found in the blood films. Sulphapyridine, 4 grammes daily (together with atebrin, 3 tablets daily), was given, and the fever and leg infection subsided in five days.

(*b*) *Filarial.*—In this condition—filarial lymphangitis—I have recently seen very favourable responses to sulphapyridine therapy in native Nauruans. As pointed out by Buttle (1939), this beneficial action is probably due to a curative effect on secondary streptococcal invaders.

Venomous Marine Animals

(*a*) *Portuguese Man-of-war* (*Physalia pelagica*).—Stings of this animal may, in my experience, give rise to severe ulceration and necrosis of the affected parts. Cellulitis and ulceration due to secondary infection may respond to sulphanilamide, and I therefore consider it a wise precaution to give the drug prophylactically in all these stings.

Case 9.—A white Trinidadian aged 21, seen on November 2, 1939, immediately after leaving the sea. The chest, abdomen, back, and arms were covered with scores of lesions from the tentacles of a Portuguese man-of-war. Sulphapyridine, 2 grammes, was given at once, followed by 1 gramme four-hourly for two days. No complications occurred.

Case 10.—A Chinese aged 23, seen on July 6, 1939, when he displayed severe cellulitis of the right forearm following a sting by a Portuguese man-of-war. Sulphapyridine, 4 grammes daily, was given. Recovery occurred within a week.

(*b*) *Sea-urchins.*—Spines of the white sea-urchin (*Tripneustes esculentus*), known in Barbados as the "sea-egg," may give rise to suppuration if not completely

removed. The use of sulphapyridine in such cases has already been described (Earle, 1940b).

(*c*) *Catfish.*—The spines of the catfish of Trinidad may produce localized cellulitis, ulceration, or gangrene. Sulphanilamide should be given prophylactically if possible.

Case 11.—A negro aged 14, seen on January 7, 1939, when he showed a cellulitis of the right hand due to a prick from a catfish spine. He was given sulphapyridine, 3 grammes daily, for two days. Cure was reported on January 9.

(*d*) *Barracouda.*—Bites from this fish often suppurate, and should receive prompt sulphanilamide therapy.

Case 12.—A Venezuelan aged 40, seen on January 8, 1939, when he displayed an infected barracouda bite of three days' duration. The area bitten was surrounded by a zone of ulceration and cellulitis. Sulphanilamide, 1 gramme thrice daily, was given, and the wound was dressed with magnesium sulphate and glycerin. On January 11 marked improvement was noted, and cure was complete on January 18.

Venomous Arthropoda

(*a*) *Insecta.*—(i) Chigoe Disease.—Ulceration and cellulitis surrounding the gravid female chigoe (*Tunga penetrans*) may respond to sulphanilamide therapy. I have seen three such cases react satisfactorily in this manner. (ii) Culicoides Bites.—Prophylactic treatment of bites of various Culicoides—*C. amazonius, C. furens, C. stellifer,* and *C. diabolicus* (Myers, 1935; Adamson, 1939)—which in Trinidad may be the starting-point of a tropical ulcer, has already been described (Earle, 1940a).

(*b*) *Arachnida.*—Several cases of encrusted scabies (gale norvégienne) have responded well to sulphanilamide therapy combined with local treatment with mitigal (dimethyl-diphenylene disulphide).

Case 13.—An East Indian labourer aged 20, seen on March 10, 1940, when he had encrusted and septic scabies of the palms, abdomen, penis, and scrotum. Sulphapyridine, 3 grammes daily, together with mitigal locally, was given. Cured in ten days.

(*c*) *Myriapoda.*—Severe cellulitis and ulceration which may follow bites of the centipede (? *Scolopendra gigantea*) have been controlled by sulphanilamide. Four successful cases have been noted, of which one is here described.

Case 14.—A negro labourer aged 30, seen on January 17, 1940, with severe cellulitis of the left hand following a centipede bite on the previous day. He was given sulphanilamide, 1 gramme thrice daily. The infection subsided in four days.

Beriberi

Bearing in mind the possible association of a bacterial exotoxin with vitamin B_1 deficiency in the production of beriberi (Low, 1936; Joyeux and Sicé, 1937), I tried the effect of sulphanilamide in a case of B_1 avitaminosis associated with cardiac lesions and oedema of the feet.

Case 15.—A female East Indian aged 25, first seen on January 4, 1939, when she complained of tingling and loss of sensation in the legs and feet, swelling of the feet, dyspnoea on slight exertion, and general weakness. The date of onset of the disease was uncertain. Examination showed a poorly built woman. The lips and conjunctivae were pale, teeth carious, and tongue furred. Firm oedema of both feet, dilatation of the right heart, and systolic murmurs were present. Pulse rate 96, tension low. Sensation of light touch was impaired in both feet and calves. Ankle-jerks were sluggish, knee-jerks were present. Ankylostome ova were observed in the stools. No malarial parasites were found in the blood. Anti-hookworm treatment was started at once. Vitamin B_1, 5,000 units daily, was injected intramuscularly for a week, and sulphanilamide was given orally for five days. On January 7 the patient had less dyspnoea and less oedema of the feet. A second course of sulphanilamide was given after three days' interval and vitamin B_1 every second day. The patient made an uninterrupted recovery.

It is of course useless to draw any conclusions from an isolated case history. However, in cases of infantile beriberi seen recently in the island of Nauru—the patients sometimes being desperately ill, showing head retraction, spasticity of the limbs, Kernig's sign, and mental confusion, in addition to liver enlargement and hydrocele—dramatic results often followed lumbar puncture and intrathecal and intramuscular injection of large doses of vitamin B_1 combined with sulphapyridine by mouth. The vitamin used alone appeared to produce far less satisfactory results. Confirmatory work is obviously necessary in this obscure condition.

LABORATORY INFECTION WITH BRUCELLA ABORTUS

BY

H. N. GREEN, M.D., M.Sc.

Professor of Pathology, University of Sheffield

The report by Huddleson and Munger (1940) of an epidemic of brucellosis in Michigan State College due to laboratory infection with *Brucella melitensis* raises in a dramatic way the problem of dissemination and the possible portals of infection in man of the pathogenic *Brucella* group.

Three Recent Cases

In this connexion the experience in my laboratory is perhaps worth recording, although in this case infection was due to the less virulent *Br. abortus*. Case 1 (H. N. G.) arose two years after experimental work had been in progress with a strain of *Br. abortus* originally isolated from a human case of undulant fever. The organism, after primary isolation in liver broth in an atmosphere of 10% CO_2, had been subcultured on plain media (agar or glycerin-agar) almost daily throughout this period, without any animal passage, and latterly grew rather better in air than in 10% CO_2. Careful precautions against accidental infection were taken, and the only direct exposure was in making frequent colonial counts from open agar plates, and in preparing and diluting small volumes of bacterial emulsions in saline from agar slopes. The attack of undulant fever did not arise after any unusual procedure or undue exposure, or after any known accidental contamination of the skin or laboratory benches. It followed a severe course, and though a trial of most of the therapeutic measures described was made, it subsided naturally after three months, immediately following the most severe pyrexial period of the illness. Sulphanilamide treatment was not, however, adequately carried out owing to sensitivity to the drug, which on one occasion produced an almost complete amblyopia lasting several hours. In the fourth week of convalescence a severe and protracted "myositis" of the lumbar muscles arose. There was no pyrexia, and the lesion was possibly allergic in nature.

Work was restarted with the same strain of organism two months after recovery, with more stringent precau-

tions than before, particularly with regard to sterilization of the benches after contact with glassware containing *Br. abortus* cultures, hand and arm ablutions, and general alertness as to the risk of infection. Gloves were worn, possible contamination by splashing was rigorously guarded against, and the bench was covered with izal for twenty-four hours after each session. Nevertheless a further case arose in the senior laboratory assistant, eleven months after the onset of the first case (i.e., after subculture of the strain for three years). This person was exposed to the organism only in the periodic preparation, from Roux bottles, of culture washings, which were poured slowly through a very wide glass funnel into an Erlenmeyer flask. At the time of infection a sulphanilamide-resistant strain which had developed from the stock strain after culture in sulphanilamide broth (Green, 1940) was being grown in bulk in Roux bottles. It is of interest that the strain of *Br. abortus* obtained from a blood culture previous to sulphapyridine treatment still retained about the same degree of resistance to sulphanilamide as the original infecting strain. This case ran a less severe course than the first, but did not become apyrexial for three months, though there was no serious relapse after giving an intensive course of sulphapyridine one month after the development of clinical symptoms.

The third case was that of another laboratory assistant, whose illness started one month after that of Case 2. He had assisted Case 2 in preparing the washings from the Roux bottles, but had not been near a culture of *Br. abortus* for one month, as all work with this organism was completely suspended and the preparation room was cleaned and disinfected when Case 2 was diagnosed. He also had a typical, fairly severe attack of undulant fever, which subsided naturally after about four months' illness.

Possible Source of Infection

There was, of course, nothing in the nature of an epidemic infection, and infection in every case may have occurred through some recognized channel such as a skin abrasion, droplet infection, or from contaminated fingers to the mouth. In all three cases, however, the individuals were not aware of any such contamination, and the second and third patients (in whom a great degree of caution had been induced by the occurrence and history of the first case) were certain that such contamination did not occur. Undoubtedly close contact with cultures was necessary for infection, as no case occurred in other members of the laboratory staff who were not working with the organism, whilst one member had assisted in the work for over two years without being clinically infected, though his serum agglutinated at one time at a titre of 1 in 100.

It is suggested as a possibility (without any concrete evidence) that infection was due to inhalation of contaminated air in the vicinity of large concentrations of *Br. abortus* growing on solid media. It is conceivable that, where the cultures had become rather dry, air currents (induced by Bunsen burners, etc.) could dislodge organisms from surface cultures. It should be noted also that Cases 2 and 3 were infected by a sulphanilamide-resistant strain. A large proportion of the cultures to which Case 1 was exposed were also grown in and subcultured from media containing sulphanilamide. It is therefore possible that after exposure to sulphanilamide the organism had become more virulent or invasive than the stock strain.

Commentary

This record does not supplement our knowledge of the alternative paths of infection in man by the pathogenic *Brucella* group, which in the natural infection is commonly via the alimentary tract. It is published rather as a warning that *Br. abortus* under laboratory conditions is a potentially highly dangerous organism and that the conditions governing its infectivity are still not completely understood. It is of particular interest that in Case 3 clinical symptoms did not appear until one month after any possible direct exposure to *Br. abortus* cultures, which would fix the incubation period in this case at a minimum of one month.

The cause of the outbreak of *Br. melitensis* infection occurring at Michigan appears superficially much more mysterious than that described here, nor do the present observations throw any light on it, except to add some support to the possibility of air-borne infection. They do, however, indicate that there may be another quite unrecognized mode of infection, the nature of which, from both the academic and the practical standpoints, it would be of value to know. Progress might be made if the details of laboratory infection of all types were more often reported.

Summary

Three cases of undulant fever are reported, due to laboratory infection by a stock strain of *Br. abortus* which had been continuously subcultured for two to three years.

In two cases the infecting strain was known to be sulphanilamide-resistant.

In no case was the exact site of entry of the organism established, and it is suggested that air-borne infection from surface cultures is a possibility.

A grateful acknowledgment is due to Prof. E. J. Wayne, who undertook the medical care of two of the cases.

A CONVULSION DURING NON-CONVULSIVE FARADIC SHOCK THERAPY

BY

GERALD CAPLAN, B.Sc., M.B., Ch.B.

House-physician at the City of Birmingham Mental Hospital, Winson Green

Following on the promising results obtained by Berkwitz (1940) of Minneapolis, an investigation is being carried out on the therapeutic effect of non-convulsive faradic shock treatment in mental disease. This method is reputed to give as good results as the ordinary cardiazol or electrical convulsive therapy without the dangers consequent on the convulsions—namely, fractures of vertebrae, lesions of the brain, and abscesses of the lung—reports of which are becoming ever more frequent (Polatin and others, 1939; Bennett and Fitzpatrick, 1939; Hamsa and Bennett, 1939; Blair, 1940).

The apparatus and technique used are very similar to those employed by Berkwitz. The faradic current is produced by an ordinary induction coil such as is used in most massage departments for muscle stimulation; and this is driven by a 6-volt dry battery. The electrodes are applied to the patient's temples, the current is switched full on, and then fifteen shocks of half a second's duration are given at intervals of half a second, varying the on–off key of the coil to make and break the current. During this period the patient is fully conscious. Each shock produces a spasmodic contraction of the muscles of the face and neck, and is described as feeling "like a bang on the head." Immediately after the series of shocks a 5% solution of pentothal sodium is injected intravenously. Enough is injected to produce a surgical anaesthesia lasting 5 to 10 minutes, and while the patient is coming round he is in an ideal state for psychotherapy. Apparently the faradic shock shakes him up and establishes

rapport, and the barbiturate produces a state of increased suggestibility. Intensive psychotherapy in the form of general and specific suggestion and persuasion is carried out in every case.

The results so far obtained are promising, but sufficient cases have not yet been treated to allow of a statistical evaluation of the efficacy of the method. It is, however, considered advisable to publish the following case at this stage as an illustration that this treatment is not entirely free from risks. Also it shows the occurrence of a hitherto undescribed sensitization to the faradic current, as a result of which a major convulsion was produced by a potential only a fiftieth of the strength of that used in normal electric convulsive therapy (Berkwitz, 1940).

Case Report

A married man aged 30, a metal-spinner, was admitted to the Winson Green Mental Hospital on August 21, 1940, as a case of acute mania, following on various environmental difficulties. There was no personal or family history of epilepsy or mental disorder. He was elated, overactive, and euphoric. He showed a well-marked "flight of ideas" and had visual and auditory hallucinations. He was disorientated for time and place, and was completely devoid of insight into his condition.

Three weeks in hospital caused no appreciable change in his condition. On September 2 a course of prolonged narcosis was started, but on its completion he appeared much the same. On September 24 some carious teeth were extracted, and on November 18 tonsillectomy was performed. By that time he had become a little quieter, but there was no significant improvement. He was still excited, disorientated, and acutely hallucinated. On January 11, 1941, a course of faradic shock therapy was started. Treatment was carried out once daily for six days. An immediate improvement was noted. After the second treatment he was much quieter and became correctly orientated. After the third session he was allowed up out of bed. After the fourth session he started to do some light ward work and his hallucinations had disappeared. The same strength of current was used every day, but it was noticed that as his mental condition improved the effect of the shocks seemed to increase. He became apprehensive of the treatment, but since he was now fairly rational it was easy to persuade him to continue.

On the fifth day the shocks had a very marked effect, and he screamed and struggled each time the current was switched on. When he recovered he seemed almost normal and discussed the various factors which had led to his breakdown. He described his illness as having been like a dream and his hallucinations as having been excessive imagination. On the sixth day he was very apprehensive, and so it was decided to cut down the current to three-quarters of the usual dose. But despite this his reaction to the shocks seemed greater than ever, and after twelve shocks he went into a convulsion which resembled in every way that usually produced by azoman or cardiazol. It consisted of a tonic stage followed by a well-marked clonic stage, the whole lasting two minutes. During this time he became pulseless and very cyanosed, his face eventually going quite black. At the end of the fit an intravenous injection of pentothal sodium was given as usual, and he woke up twenty-three minutes later with complete amnesia for the actual period of treatment.

Subsequently he has appeared quiet and rational and has discussed his illness at great length with perfect insight; but he has complained bitterly of pain and tenderness in his upper dorsal vertebrae. He says he feels as though he has been "kicked in the back." A radiograph showed no abnormality.

In view of his satisfactory mental condition and the possibility of further convulsions producing crush fractures of the vertebrae it was decided to terminate the treatment at this stage.

Discussion

Berkwitz (1940) has shown that the resistance of the patient's head between the two electrodes is fairly constant at 10,000 ohms and that the average current flowing during a shock is about 10 mA. A much higher current than this is often used clinically in muscle and nerve stimulation without producing tissue damage, so the chief benefit claimed for faradic shock treatment is its safety, in that the current used is too small to produce burns or unconsciousness or convulsions.

The therapeutic efficacy of the treatment in the above case is undoubted. A bad case of acute mania which had resisted other forms of non-convulsive therapy was brought back to normality within six days; but with increasing normality came a strange increase in sensitivity to the faradic current, and finally a major convulsion, with all its dangers, was caused by a current three-quarters of the normal strength—a current which other patients can tolerate with equanimity. It would appear as though some cumulative physical change which was associated with the improvement of his mental condition was taking place in the patient's brain, and that this change also involved his sensitivity to faradic stimulation.

Further investigation along these lines may well lead to some satisfactory explanation of the mode of action of shock and convulsive therapy in mental disorder.

Summary

A brief account is given of faradic shock therapy. The reason for its preference to other forms of similar therapy is that it normally does not give any dangerous convulsions.

A case of acute mania successfully treated by this method is described.

An account is given of how the patient became increasingly sensitized to the faradic current until eventually a small current produced a major convulsion.

My thanks are due to Dr. J. J. O'Reilly, medical superintendent of Winson Green Mental Hospital, for his help and for permission to publish an account of this case.

Clinical Memoranda

Convulsions under Anaesthesia

As the subject of ether convulsions has been much to the fore of late, and there is little agreement among writers as to the pathology or treatment of this grave condition, it may be of some value to record the first case of this kind that has occurred under my care.

CASE REPORT

The patient, a weedy boy aged 12, was admitted to hospital extremely ill with acute appendicitis of three days' standing. He appeared severely toxic; the temperature was 100°, the pulse 124, and he had marked right-sided abdominal rigidity. Cardiac examination showed *gross dilatation of the heart to the anterior axillary line*, associated with a soft systolic murmur all over the praecordium. This appeared to be the result of rheumatic carditis, possibly following a severe attack of measles at the age of 6.

Premedication consisted of atropine sulphate, 1/100 grain; and owing to his extremely poor general condition an intravenous glucose-saline drip was started before operation and was continued. Anaesthesia was quietly induced with 5 c.cm. of ethyl chloride and maintained by open ether on a lint-covered mask, covered again by lint and towel. Oxygen was administered under the mask continuously, and at no time was there any sign of cyanosis or hyperoxygenation. The anaesthesia

was maintained at the level of the second plane of the third stage, and no difficulties arose during the first hour.

Owing to the situation of the appendix and its condition, and that of the abdominal contents, the operation proved difficult and prolonged; the pulse became gradually more rapid until at the end of an hour it was over 200 and almost uncountable. Suddenly at this stage convulsions started in the right leg, immediately becoming general, rapid, and violent. While evipan was being prepared I removed the extra coverings from the mask and administered a few drops of chloroform, without any change occurring in the convulsions. I then removed the mask and ran in oxygen through the airway. With some difficulty, owing to the convulsions, I succeeded in introducing 2 c.cm. of evipan into an arm vein. Cessation of the convulsions was immediate and dramatic. I then introduced into the drip-tube a further 3 c.cm. of evipan, and as the pulse was very poor I also added to the drip-bottle 2.5 c.cm. of coramine. The patient's condition improved rapidly; the pulse fell to 184, and the operation was proceeded with, being completed at the end of two hours. Oxygen administration had been continued, and only a few occasional drops of ether on the mask were required to maintain a sufficient depth of anaesthesia. The patient returned to bed a good colour, with a pulse of 180.

This case is of further interest in that half an hour after his return to the ward a further convulsion supervened. This was a single tonic spasm of the whole body, with face florid, tongue protruding, eyeballs turned up, and head retracted. The pulse was imperceptible. Oxygen was administered through a nasal catheter, and in about a minute the convulsion passed off: the pulse returned and improved quickly, and had settled down to 144 in fifteen minutes. The intravenous drip was continued and 1/6 grain of morphine was given hypodermically, and the patient settled down to a perfectly peaceful return to consciousness. Next morning (twelve hours later) his pulse was 124 and the temperature 100°, and there was amazing clinical improvement. No post-anaesthetic complications ensued beyond slight chestiness, which quickly cleared up.

Of all the possible causes of convulsions that have been suggested the outstanding features in this case appeared to be (1) toxaemia; (2) cardiac defect and poor general condition; (3) prolonged operation. As to the cause of the second convulsion, I should be glad of any suggestions that might elucidate its cause and nature, and would like to be informed whether in cases of this type the preliminary administration of an intravenous barbiturate or even a suitable dose of one of the slower-acting barbiturates might have been an effective preventive measure.

An Unusual Case of Cystic Disease of the Pancreas

The following case seems to be uncommon enough to merit being placed on record.

CASE REPORT

At 11 a.m. on March 7, 1940, I was called in to see a Hindu boy aged 11, a relative of one of our compounders living in hospital premises. He complained of intermittent pain in the abdomen and of an oval lump, about half the size of his head, extending downwards from the right costal margin. He had vomited twice. The lump was tender, dull to percussion, tense, and slightly movable, and its relations and attachments were uncertain. It was clearly defined to the right, but less so to the left, and it was possible to insert the fingers between it and the liver. The rest of the abdomen was not tender or "boarded." The pain, though fairly severe when present, was not sufficient to double him up. His temperature was 100°, rising later to 101.4°, and his pulse 120, rising later to 140. He had been all right after his evening meal the day before, but during the night vague abdominal pain had set in, disturbing his sleep from time to time. In the morning his father had discovered the lump in his abdomen, which apparently had not been there before. There was a history of worms having been passed some time previously.

On examination the faeces contained no ascaris ova, and the urine was normal. The leucocyte count was 20,000 per c.mm. Nothing abnormal was found per rectum. A radiograph was blurred owing to the child's inability to hold his breath, but it showed an opaque shadow at the site of the lump.

The differential diagnosis seemed to be between (1) obstruction due to intussusception, impaction of a mass of ascarides, or internal strangulation, and (2) retrocaecal appendix abscess; none of these, however, appeared to fit the clinical condition accurately. We gave the child an anaesthetic (ethyl chloride) and washed out his stomach and bowels, examining him again while under the anaesthetic, without affording him any relief and without eliciting any further information.

As his condition was getting worse—pulse, temperature, and respirations rising, and distress increasing—I operated at 8.30 p.m. A free right paramedian incision gave insufficient access to explore the lump adequately, but it was definitely located behind the ascending colon, which it had been compressing against the anterior abdominal wall. The bowels, appendix, and gall-bladder were healthy, and there was no free fluid in the peritoneal cavity and no apparent cause of the symptoms of obstruction except the pressure of the lump against the ascending colon and duodenum.

The lump itself was obviously cystic, and at first sight suggested the possibility of hydronephrosis, but it was found definitely not to be associated with the kidney. It was made up of innumerable loculated thin-walled cysts. I aspirated two of these from a point lateral to the ascending colon. One contained altered blood and necrotic material and probably bile, and the other contained clear fluid slightly stained with fresh blood. This aspiration reduced the size of the mass sufficiently for a better exploration, whereupon it became clear that the tumour was associated with the head of the pancreas and had worked its way retroperitoneally behind the ascending colon and still further to the right. The peritoneum covering the pancreas had an unhealthy "sago-pudding" appearance.

The patient's condition by this time was bad, and it seemed impossible to dissect out the cystic mass in time, so I decided to aspirate as many of the cysts as I could reach from the right side of the ascending colon, and trust to Providence for the result. The cysts varied in size from a pea to an egg. Some contained clear fluid. Others were blood-tinged or were full of altered blood, bile, and necrotic material. By the time I had aspirated as many cysts as I could reach the head of the pancreas had become, as it were, deflated. I inserted a drain in the right loin and closed the wound. Several injections of soluseptasine were given as a protection against possible suppuration, as well as anti-shock treatment.

I expected the patient to die, but actually he had no more trouble than could be expected from the trauma of the operation itself. The discharge from the drain ceased on the second day. His temperature, pulse, and respirations were normal from the third day, and thereafter he made an uneventful recovery, and when I last saw him on May 2 he was remarkably well. He had no discomfort, and no sign of the tumour could be made out.

COMMENTARY

I suggest, as the most probable explanation of the case, that haemorrhage and inflammation occurred in the head of the pancreas, which was already the seat of cystic disease—cystic adenoma. The cystic mass probably grew in size, working its way over to the right and displacing the peritoneum covering the duodenum, thereby causing pressure on the duodenum and pressure-obstruction to the outflow of bile and pancreatic juice from the common bile duct and so damming them back into the pancreas. This would cause digestion and haemorrhage. It also explains the presence of bile in some of the cysts, and the sudden increase in the size of the tumour clinically noted. The case, however, seems so unusual that I would be most interested if some expert surgical pathologist would comment on it.

I am obliged to Dr. Dyson, chief medical officer of the M. & S.M. Railway, for permission to publish the case, and to my Indian medical staff for their part in dealing with it and discussing it with me.

Reviews

DIAGNOSTIC BACTERIOLOGY

Methods for Diagnostic Bacteriology: A Complete Guide for the Isolation and Identification of Pathogenic Bacteria for Medical Bacteriology Laboratories. By Isabelle G. Schaub, A.B., and M. Kathleen Foley, A.B. (Pp. 314. 15s. net.) London: Henry Kimpton. 1940.

This is a new kind of book. It sets out simply to describe the methods employed at the Johns Hopkins Hospital, Baltimore, for identifying bacteria in material from patients, and the fact that this exposition occupies over three hundred pages is due to leaving every left-hand page blank for the user's own notes and to the thoroughness with which the authors' task has been carried out. They begin by describing the methods employed for each kind of specimen, and follow this with instructions for identifying main types of bacteria. A section on serological diagnosis deals only with agglutination and precipitin tests, and gives particular attention to determining the type of pneumococci in various materials. A concluding section describes the preparation of culture media, stains, and other reagents.

Probably no two institutions use quite the same methods in this kind of work, and every bacteriologist has his foibles in technique: his methods may in some points be intrinsically superior to other people's or merely better for him because he is better practised in them. Hence no one is likely to admit that each of the proceedings described here is the best of its kind. Points in this book most likely to be criticized are the omission of bile or bile salts from media for cultivating typhoid bacilli from blood, the use of methylene-blue for staining diphtheria bacilli (it is impossible to dispute that Pugh's or Albert's stain gives a much more characteristic picture); a method for "washing" sputum which does not wash it at all but only employs rather cumbrous means to make a saline suspension of the whole specimen; the use of the wire loop as a spreader (many people find a bent glass rod much more serviceable); a hanging-drop technique which does not seal the preparation and therefore removes its chief advantage, which is that it can be incubated; and the absence of any reference to degrees of agglutinability in bacterial suspensions and their standardization. A more general criticism is that cultural methods advocated are too complex: there are shorter roads to the same results, and intelligent forethought or the study of direct films should enable the bacteriologist to use a single culture medium instead of three, as sometimes advocated here. On the other hand, almost everyone has probably something to learn from this book; it is of great interest as revealing the methods employed in a leading laboratory in the U.S.A., and its unique form renders it a ready source of information in difficulties which arise almost daily at the laboratory bench.

THE LIFE OF AN INVALID

The Glorious Bondage of Illness. By France Pastorelli. A translation of *Servitude et Grandeur de la Maladie.* Preface by Pierre Sanson, O.P. (Pp. 224. 2s. 6d. cheap edition.) London: George Allen and Unwin, Ltd. 1941.

The tragic nature of this book is enhanced by representing a partial failure as an unqualified success. It is the record of the struggles of an able woman to adapt herself to the life of an invalid when suddenly arrested in a musician's career by a form of heart disease, involving frequent and severe anginal attacks, which it is stated "keeps her life in constant jeopardy." The first part is called "The Drama of the Inner Self," which the author herself thinks ought not to see daylight but of which, owing to the solicitude of friends, she publishes the less intimate parts. It is written in a spirit of religious exaltation. The second part, "The Drama of the Environment," however, shows that the triumph over the self has not been completely successful, for the greater part of it is occupied by vivid complaints of the attitude which the healthy adopt towards the sick. Many of these are doubtless justified, but they do suggest a sublimation less perfect than is claimed by the writer of the preface. However, to make amends, the last chapter is devoted to some useful and helpful advice to other invalids. The English title rather exaggerates the tone of the original French one, *Servitude et Grandeur de la Maladie*, but we cannot help feeling that sentences such as this have an element of, probably unconscious, dramatization: "The agony in the Garden of Gethsemane, the help vanishing when the strong appeal is made, the nearest and dearest friends asleep, the reiterated protestations and denials of St. Peter, these are tragedies which we have lived through again and again." The impression is left on the mind that the author is right in saying that a trench is dug by illness between the invalid and the healthy; indeed, the trench seems so wide in these pages that one wonders how it can really be bridged. "'Take care,' a friend said to me in words which showed that she did not in the least understand. "You seem to think that sickness is in itself a higher kind of life.' 'Certainly not!' I replied." We wonder whether that friend was wise in trying to underrate a compensatory mechanism.

The author naturally has a wide experience of doctors and speaks well of the majority. She gives some good examples, however, of things that doctors should *not* say to patients.

PICTORIAL AIDS TO ANATOMY

Illustrations of Regional Anatomy. By E. B. Jamieson, M.D. Third edition. Section I. Central Nervous System. (49 plates. 7s. 6d., plus 6d. postage.) Section II. Head and Neck. (64 plates. 15s., plus 7d. postage.) Section III. Abdomen. (41 plates. 6s., plus 5d. postage.) Section IV. Pelvis. (34 plates. 4s., plus 5d. postage.) Section V. Thorax. (31 plates. 4s., plus 5d. postage.) Edinburgh: E. and S. Livingstone. 1941.

Notwithstanding difficulties arising from the demand for skilled labour and material during wartime, the first five sections of Dr. E. B. Jamieson's *Illustrations of Regional Anatomy* have been duly produced, and contain many valuable additions and improvements. No fewer than 300 colour-blocks have been prepared for this edition. Some of the enlargements showing small details of parts such as the middle ear, or the relations of the vessels to the gall-bladder and its duct in the region of the first part of the duodenum, are especially worthy of note, and also the beautifully executed plates showing the sacral plexus on a dark background. Some of the plates described as "schematic" are perhaps too conventional, and give unmistakable evidence of having been composed to fit in with common conceptions rather than the more ideal method of drawing from actual specimens and afterwards, when necessary, simplifying by the suppression or omission of unwanted details. The general excellence and popularity of this work are, however, evidenced by its large sale, estimated to be over 45,000. This is probably due in the main to its value as a pictorial aid to a quick comprehension of the necessarily lengthy descriptions of anatomical text-books. The latter are, however, indispensable for gaining a sound knowledge of the significance of the relation of the structures which are so skilfully displayed in the coloured plates. Verbal descriptions, moreover, provide an opportunity of giving some indication of the practical application of the topographical knowledge acquired by dissection

the use of illustrations. It is also important that it ould be generally realized that there is a real danger making anatomy too easy, and that parts seen during peration have a very different appearance from that hich might be expected from impressions gained solely om diagrams and coloured plates. The plates therefore ust be regarded as being supplementary to practical ork in the dissecting room, carried out with the help of good descriptive manual, rather than being complete in emselves. Employed in this way and as a reminder of nowledge previously acquired they should be of great alue to both student and practitioner.

CHEMISTRY AND MEDICINE

Chemistry and Medicine. Papers presented at the Fiftieth Anniversary of the Founding of the Medical School of the University of Minnesota. Edited by Maurice B. Visscher, Professor of Physiology at the University of Minnesota. (Pp. 296. 28s.) Minneapolis: University of Minnesota Press; London: Oxford University Press.

he University of Minnesota in 1939 celebrated the fiftieth nniversary of the establishment of its medical school, nd has published in volume form a series of papers resented on that occasion. These deal with the influence f chemistry on the modern development of medical cience. Various selected aspects of this subject are dis-ussed, and the volume provides interesting evidence of he extent to which medicine has become dependent upon hemistry.

Many of the most important recent advances in medicine re generally recognized as examples of applied chemistry ulphonamide therapy, which is described by Prof. Long, s an example of this type. The dependence of the science f vitamins on organic chemistry is equally clear, and in his case a table provided by Prof. Smith is of interest n that it demonstrates the remarkable acceleration that as occurred in the isolation and synthesis of vitamins. The existence of the three original vitamins—A, B, and C —was demonstrated about 1912, but their synthesis was ot achieved until twenty-five years later. On the other and, vitamins B_6 and K, proved to exist in 1936, were solated and synthesized within three years. The table actually lists six vitamins that have been synthesized during he past five years. This remarkable acceleration in progress is due to the great advances in analytical methods, chief among which is the perfection of methods of spectrum analysis. Endocrine secretions are not dealt with in this volume, but their history shows a similar, if less spectacular, acceleration in the rate of progress due to advances in organic chemistry. The dependence of chemotherapy, "vitaminology," and endocrinology upon organic chemistry is so well recognized that it needs little comment.

Other chapters in the book, however, summarize the importance of chemistry in fields where its influence is not so obvious. Prof. Heidelberger shows that immunity is slowly but steadily being reduced to a chemical problem. This is largely due to the work of Landsteiner, who found that artificial antigens could be constructed by combining proteins with chemicals. This work, combined with microchemical analysis, has made it possible to study the antigen-antibody reaction as a problem in quantitative chemistry and to write empirical formulae for the composition of the precipitates resulting. The subject of filterable viruses, discussed by Prof. Green, is another field which is influenced profoundly by protein chemistry, as in this case it has been found possible to crystallize viruses and to estimate their molecular weight. Finally, Prof. Cannon, in a short article on the chemical mediation of nerve impulses, assembles a strong case in support of the view that the transmission of impulses from a nerve cell to another cell is served by the liberation of acetylcholine and adrenaline. This is, of course, a highly controversial subject, but the author outlines his case with remarkable clarity. The transmission of nerve impulses was regarded only a few years ago as a problem of electrophysics, and the possibility of treating it as a problem of organic and enzyme chemistry is remarkable evidence of the change that modern chemistry is effecting not only in medicine but in the fundamental problems of physiology.

Notes on Books

The official *Medical Register* for 1941 has now been published on behalf of the General Medical Council by Constable and Co. at 21s., post free 22s. 6d. The table printed in the introductory section shows that 2,384 names were added last year. New registrations numbered 1,323 in England, 673 in Scotland, 315 in Ireland, 57 on the colonial register, and 16 on the foreign register. The total number of names on the *Register* at the end of the year was 64,679—1,319 more than in 1939. The number of names removed from the *Register* during 1940 was 1,102; of these 1,071 were deleted on evidence of death, 24 for failure to comply with the inquiries of the registrar as to cessation of practice or change of address, and seven were struck off under the disciplinary powers conferred by Parliament on the General Medical Council.

The first edition of *The Diagnosis and Treatment of Pulmonary Tuberculosis*, by JOHN B. HAWES and MOSES J. STONE, was published in 1936 and was very favourably reviewed in these columns. The second edition recently published (Henry Kimpton, 12s. 6d.) has been revised by Dr. Stone. It is our opinion that this small volume has not gained in value by this revision. The excellent presentation of "essentials" has suffered by introducing the classifications of "childhood and adult types of tuberculosis" and "productive and exudative types of tuberculosis." In particular the latter distinction must lead to confusion in the proper application of collapse therapy. Further, in an elementary textbook in which the authors speak of "pneumothorax or 'gas treatment'" and of "thoracoplasty, or the rib operation," the wisdom of presenting a large number of radiographs might be questioned. Their choice, moreover, appears to have been little studied by either publishers or author, since some reproductions are of positives, others of negatives; some postero-anterior, others anteroposterior; some of excellent quality, others obviously of films taken either with a very poor technique or with apparatus dating from the early days of chest radiography. Despite these criticisms this remains probably the best small book on the subject in English.

Three years ago the fourth edition of *Operative Surgery*, by J. SHELTON HORSLEY and ISAAC A. BIGGER, earned our favourable comment; now a fifth edition brings it up to date and includes such recent surgical procedures as ligation of the patent ductus arteriosus, which was first successfully performed in 1938 by Gross of Boston, and an account of the operation for performing extrapleural pneumothorax, a procedure which, although originally carried out in 1891 by Tuffier in Paris, did not come into its own until about three years ago and now apparently has a definite place in the surgery of phthisis. Neurosurgery is brought up to date in a section written by Dr. C. C. Coleman, urology in that by Dr. Austin I. Dodson, orthopaedics in a section by Dr. Donald M. Faulkner, and plastic surgery in articles by Dr. John S. Horsley, jun. This delightful, clearly and well illustrated, and easily read two-volume work is the best of its kind that we know. All that we said in favour of the fourth edition, and as our American friends might graphically say, "and then some," applies to this new edition. If asked by one about to begin surgical practice to recommend a really good modern guide to its operative aspects, we should unhesitatingly name this edition of Horsley and Bigger. It is published in two volumes at £4 10s. by Henry Kimpton.

TREATMENT OF BURNS

Interest in burns has been greatly stimulated by their increased incidence due to the war, and much discussion, not always tempered by clear thinking, is taking place as to the merits of this or that treatment. The variation in type and distribution of burns is at present resulting in personal experiences which, because of their limited nature, give a one-sided view of a large problem, and from which conclusions may be drawn having less general validity than their sponsors realize. Thus the experience of a surgeon dealing with R.A.F. personnel may be very different from that of one dealing with the victims of their opponents. Recent discussions and contributions to the medical press have shown dissatisfaction with established methods of treatment, and the war has seen already many attempts to improve upon them. At a time when there is no general agreement as to the best methods it may be well to pause and take stock of the problem as a whole.

Two features distinguish thermal from other injuries: their special danger to life if extensive, and the crippling nature of their scars in many parts of the body. The two aspects of treatment—saving of life and saving of function—cannot be separated, but either may predominate even to the exclusion of the other. There are burns that menace life but not function (for example, a large superficial body burn), others that menace function but not life (for example, burns of the hands): these examples are given with the suggestion that uniformity of treatment of burns is neither desirable nor possible. The danger to life depends on extent rather than depth of burn, and to a smaller degree on situation. Burns kill by shock, toxaemia, or sepsis. The treatment of shock due to burns is on the same lines as for other forms of traumatic shock, but often merging with shock is the peculiar state known as burn toxaemia, which, while presenting some of the features of the former condition, has additional characteristics, notably fever and evidence of liver damage. There are three theories as to the cause of burn toxaemia: first, that it is due to a disturbance of the fluid and electrolyte balance of the body; second, that it is the result of sepsis; and, third, that a specific toxin is elaborated in the burnt tissues. Elkinton[1] has shown that correction of the recognized abnormalities in the blood does not prevent the condition, and Wilson, Macgregor, and Stewart[2] have observed it in cases in which cultures from the burns and blood were sterile. The liver damage described post mortem by Wilson *et al.* and confirmed in life by liver-function tests by Wolff, Elkinton, and Rhoads[3] is suggestive of the action of a toxin and has led to the recognition of glucose as an important part of the treatment of severe burns.

[1] *Bull. Ayer clin. Lab.*, 1939, **3**, 279.
[2] *Brit. J. Surg.*, 1938, **25**, 826.
[3] *Ann. Surg.*, 1940, **112**, 158.

At the present time, however, discussion centres round the local rather than the general treatment of burns, and has become a little heated between the advocates and critics of coagulation methods. As there is a trend of opinion away from these methods it is important to remember that one of the chief claims made for tannic acid was its reduction of mortality. Wilson[4] has produced evidence of this, and McClure[5] in a recent summary of the position points out that U.S.A. statistics showed a fall in the annual number of deaths from burns after the introduction of the tannic acid treatment by Davidson, although since 1933 there has been no further fall.

The problem of local treatment depends, first, on the depth of the burn. If there is no full-thickness loss of skin good healing should follow any method that prevents sepsis. Healing, moreover, should be rapid, since except for raised epidermis there is no macroscopic death of tissue and no sloughs to separate. In this type of burn rapidity of healing may eventually decide the choice of method. Although the deep layers of skin survive they are no barrier to the entry of organisms, and it is not sufficiently recognized that infection of a superficial burn may convert a partial into a full loss of skin thickness. This risk is particularly serious when infection appears under a coagulum, since the damage may occur before the sepsis is recognized. This phenomenon can be seen in tanned donor areas of razor grafts in which there is no doubt as to the depth of the original injury. When the whole thickness of the skin and deeper structures are destroyed sepsis may be more difficult to control, and, furthermore, healing cannot take place until the dead tissue has separated. These burns present two further problems: the removal of sloughs, and the covering of the resulting defect, which often calls for skin grafting. The early separation of sloughs and repair of the defects assume special importance in those parts where function is endangered—the hands, the face, and the flexures. Now it may well be that sepsis hastens the separation of sloughs and that its prevention will delay it. Most surgeons have seen small areas of dry gangrene of the skin due to heat or pressure (both occur in air-raid casualties) which remain clean and take weeks to separate, and most, too, have noted the rapidity with which a large mass of tissue may separate from a septic pressure sore. It is likely, therefore, that the control of sepsis will throw into prominence the problem of separating sloughs, and methods of accelerating this process are already being studied. In small deep burns the slow natural progress of the lesion has led some surgeons to excise and graft immediately.

In superficial burns we require of local treatment no more than protection of the lesion from further injury, mechanical or infective, until healing is complete, and of methods which fulfil these requirements preference will be given to the quickest. In deep burns we need control of sepsis, and rapid removal of dead tissue and its early replacement by grafting or artificial stimulation of natural healing. Coagulation methods fulfil these requirements in part only. They give a fair protection against secondary infection but do not control that introduced before treatment, and it has

[4] M.R.C. Reports, 1929, No. 141.
[5] *J. Amer. med. Ass.*, 1939, **113**, 1803.

always been recognized as an essential part of the treatment that the burnt surface should be rendered sterile or nearly so by careful cleansing before the coagulating agent is applied. It has also been claimed for these methods that they provide optimum conditions for healing by splinting the affected part. This is probably beneficial in the trunk and limited areas of the limbs, but splinting of the hands for the long time during which a coagulum may remain adherent would be tolerated for no other form of injury, because of its crippling effect on function. This is one reason why the E.M.S.[6] advised that hands should not be tanned. Another is that tan contracts and may produce further damage by causing ischaemia. This has been disputed and is difficult to prove, but the splinting effect of the tan and the very long time it takes to separate in deep burns should alone condemn the method for burns of the hands.

The failure of coagulation methods to control sepsis may be eliminated by the use of drugs of the sulphonamide group, as recommended in the latest E.M.S. memorandum on burns.[7] The use of these drugs is the most important novelty in the treatment of burns, and an example of its application is described in this number by Robson and Wallace. Whether their paste has any virtue apart from its sulphonamide content is doubtful, nor is it clear why albucid is preferred to other available sulphonamides. Most of their cases are of superficial burns, and the method appears to fulfil the requirements which we suggested for this type—namely, protection of the lesion from mechanical and bacterial injury—and appears to be applicable to all parts of the body. With regard to their implied aspersion on the saline treatment, perhaps the authors have not realized that when this is properly carried out it includes dusting the burn with sulphanilamide whenever the tulle gras is changed (E.M.S. memorandum). It seems possible that with the addition of sulphonamides any method of treating burns will be improved, and even carron oil may return to favour.

Apart from the use of applications containing sulphonamides such as that described by Robson and Wallace, the most widely used alternative to coagulation at present is the saline method described in the E.M.S. memorandum. This aims at controlling sepsis with sulphanilamide and keeping the lesions bathed in physiological salt solution until healed or ready for grafting. The details vary with the part of the body burnt, but one or more daily saline baths are given to the injured parts, which are kept moist between the baths with saline dressings laid over tulle gras to prevent adhesion. It is to be hoped that before long some results will be published of this treatment, which was advocated by several speakers at a recent discussion at the Royal Society of Medicine. A variant of this method is that described by Bunyan,[8] who maintains constant bathing of the lesions in saline and hypochlorite solutions in oiled silk envelopes adapted with much ingenuity to various parts of the body. From time to time the envelope is flushed out with solution to remove discharges and debris. Two advantages are claimed for this method: that it controls sepsis without the addition of other drugs, and that it hastens the separation of dead tissue.

It has yet to be shown that any of the alternatives to coagulation therapy are as beneficial when the burn is extensive enough to endanger life, and the E.M.S. memorandum suggests that coagulation is still the method of choice for such cases. In the war burns about which there has been dispute, however, the risk is nearly always to function rather than to life. This is particularly true of the burns of the hands and face, which are mostly caused by short exposure to very high temperatures—either flash burns, against which clothing protects the body, or flame burns as sustained by air personnel. The flash burn may involve the whole hand without anywhere destroying full thickness of skin; if this is tanned, the hand is enclosed in a semi-rigid glove which prevents movement and may, as it contracts, produce dangerous constriction. In this way a superficial burn may result in a stiff hand which takes months to recover, if it ever does. Even worse will be the stiffness after deep burns of the hands, from which the coagulum separates very slowly. It is no answer to this criticism to say that many tanned burns of the hands do very well. A small percentage of disasters is enough to condemn any method.

HEALTH AND SAFETY IN FACTORIES

No one will be surprised to learn that there was a large increase in industrial accidents in the early part of the war. During the first six months the number of non-fatal accidents in factories rose by 42%, and of fatal accidents by 13%, compared with the six months from September, 1938, to February, 1939. One thinks immediately of the black-out, an experience without precedent in the history of this country, pressing hardest of all perhaps upon those engaged in industry, affecting the physical and psychological conditions of their daily work and hindering and endangering their transport. But the black-out causes its accidents outside rather than inside the factories, and in the annual report of the Chief Inspector of Factories for 1939, which has only lately been published,[9] it is placed sixth among the seven causes of increased accidents in wartime. The others are the increased number of persons employed, with extension of hours of work, neglect of safety precautions due to speeding up of production, shift of working population from relatively safe to accident-producing industries, fatigue and mental stress, and the bringing back into industry of machines in various stages of obsolescence.

During 1939 as a whole there was an increase amounting to 17% of fatal and 7% of non-fatal accidents, but there was actually a decrease of 2% in the number of accidents to young persons, one of the first-fruits of the tightening of safety conditions brought about by the new Factories Act. The industries in which accidents were most numerous were those concerned with war production. In the manufacture of aeroplanes, for example, the accident rate went up by 20%. The total number of accidents in industry

[9] Cmd. 6251. Annual Report of the Chief Inspector of Factories for the Year 1939. H.M. Stationery Office. (1s. net; postage extra.) 1941.

(meaning those which were either fatal or disabled the workman for more than three days) was 193,475, of which 1,104 resulted in death. The largest number (25,358) were due to persons falling; building operations contributed most to this form of accident. There were 6,742 accidents in the cotton industry, but only 23 were fatal, and in the woollen industry, with 3,884 accidents, the death roll was only 18. One fact which has emerged from an inquiry into the subject is that the number of accidents reaches its maximum in the middle of the morning or afternoon—that is to say, some three hours after starting or restarting work. The more serious by-product of the black-out so far as workers in factories are concerned is the effect on health. In many cases, at the beginning of the war, factory windows were obscured with black paint, which entailed working under artificial light all the time, with unhappy consequences both for health and output. One irony of the situation is that modern factory architecture had been advancing towards large window-space, which had greatly improved the conditions, but meant a bigger problem and a bigger deprivation when lighting restrictions came in; while another irony was that modern housing estates had been placed outside industrial areas, greatly to the workers' advantage until the black-out imposed what was virtually a prolongation of hours of work and strain. A well-deserved tribute is paid in the report to the philosophical way in which the workers have accepted the position and made the best of it.

The black-out adds to the strain of war work by interfering with ventilation, increasing the risk of gassing in various occupations, raising the temperature of workrooms to an uncomfortable level, and depriving the workers of ordinary daylight. But conditions have been improving in this respect, and no doubt the Chief Inspector's report for 1940 will describe not merely an adaptation of workers to bad conditions but a better adaptation of conditions to workers' normal requirements. Dr. J. C. Bridge, Senior Medical Inspector, whose section in these annual reports is always looked forward to as a valuable commentary on industrial medicine, says that before the outbreak of war the number of accidents from gas or fumes was below previous years, but during the last quarter of 1939 the number of reported cases of gassing was approximately double that of any previous quarter of the year. Where localized exhaust ventilation is effectively installed the measures taken to obscure lighting may be without detriment, but where natural ventilation is relied upon, as in blast furnaces, the tale is very different. The total number of cases of gassing reported during the year was 184, with 11 deaths. Carbon monoxide was the agent in 84 cases, chlorine in 29, and nickel carbonyl in 10. The first case of fluorine osteosclerosis in this country was brought to the notice of the Department during the year, and an investigation was still proceeding when the report was written.

Cases of industrial poisoning or disease notifiable nder Section 66 of the new Factories Act showed a very considerable fall during the year. There were 109 notifications of lead poisoning, with 6 deaths. Only 15 of these cases, with 1 death, were due to the painting of buildings, an occupation which, two decades ago, was attended by more than 20 deaths a year. Cases of anthrax numbered 37, with 5 deaths; epitheliomatous ulceration, 160 cases, with 31 deaths, chiefly in the pitch industries; and chrome ulceration, 159 cases, chiefly in chromium plating, with no deaths. The number of deaths from silicosis—439—remained about the same as in previous years. Of these deaths 197 occurred among coal miners, 70 among sandstone masons, and 51 among men engaged in the manufacture of pottery. The number of voluntarily reported cases of dermatitis continues to increase: in 1939 it was nearly 3,000. The largest numbers occurred in chemical manufacture, mechanical engineering, and the manufacture and making up of textiles. The baking and biscuit trades contributed only a little over 4% of the cases.

The number of young persons, between 14 and 16 years of age, examined for certificates of fitness during 1939 was 406,575: the rejections numbered 5,681, and the conditional or provisional certificates 15,702. The chief cause of rejection was pediculosis; next come diseases of the eyes and eyelids. Defective bodily development accounted for only a little over 2% of the rejections. The term "medical supervision" is still vague and indefinite. Dr. Bridge points out that the frequent practice of engaging a medical man to be available for the treatment of accidents or to examine workers in relation to liability to compensation cannot be considered as a form of medical supervision. Many firms have gone further by engaging the part-time service of a medical man to supervise first-aid arrangements as well as to undertake examinations. A limited number have enlisted the whole-time service of a doctor whose duty it is to prevent and alleviate sickness and injury. Firms manufacturing foodstuffs and drugs are naturally more likely to realize the value of this whole-time supervision, but many other undertakings of equal size, concerned with engineering, paper-making, artificial silk, and other industries, have taken similar steps. Medical supervision for specific purposes plays an important part in factories where special work of national importance has to be done, and the Ministry of Supply has appointed whole-time medical officers in factories, some of which require more than one medical officer, and some have both men and women medical officers. As for other firms, where the occupation presents little or no risk to health the services of a trained nurse may be utilized for the care of the workers, and Dr. Bridge thinks that such care, when it is, as it should be, linked with a call on the local medical practitioner, must often suffice.

TREATMENT OF G.P.I.

The death of the distinguished emeritus professor of psychiatry in the University of Vienna, Prof. Wagner-Jauregg, brings to mind one of the major therapeutic discoveries of our time. He will always be remembered as the pioneer in the treatment by artificial malarial infection of general paralysis of the insane, "dementia paralytica." These names themselves mark the gloom of the outlook before his work fructified, while the arguments on terminology—whether it shall be called "cerebral parenchymatous syphilis" or more briefly "paresis," instead of by its traditional name—are evidence not only of changing pathological knowledge and conceptions but also of the new view of the course and prognosis that malarial therapy

has induced. Like a number of other important discoveries it was the result of the application of a casual observation made by others before him. Bumke[1] quotes Jakobi, Ludwig Mayer, Schule, and v. Halban as having observed that manic cases especially of G.P.I. were favourably influenced by intercurrent febrile infections. But often in the history of scientific discovery the initiative and energy needed to follow up an apparently small observation and to realize its significance have not been found in the original observer. Wagner-Jauregg tried a number of febrifacient means, including tuberculin, and his conclusion that malaria is at least as satisfactory as any other method has not really been superseded. Rivals of the bacterial and virus sorts have not established their position. The most recent competitor of this type has been a Rickettsia virus, which has the advantage of cultivability *in vitro*; but the method which, after malaria itself, appears to have been most used (apart from the pharmacological non-pyrexial one with tryparsamide) has been the electrical one of producing fever; this has the advantage of being subject to readier control than any of the others. Very recently what appears to be a model of team-work, comprising a group of hospitals and the public health service, has been exhibited in the U.S.A. in an investigation of the result of the electrical as opposed to the malarial method of producing pyrexia (O'Leary *et al.*[2]). In a total of 1,420 cases, of which 1,100 were treated by malaria and 320 by "artificial fever" (oddly enough the precise method is nowhere stated in the paper), the results were closely similar with patients suffering from mild and intermediate degrees of general paralysis, but very much in favour of diathermy in patients with a severe degree of the condition—i.e., those showing considerable mental deterioration.

The history of the treatment of general paralysis is one of continued advance since 1917, after a long plateau of time in which clinicians first learned to elaborate the description of a fascinating but devastating disease; then bacteriologists demonstrated the causal relation to it of syphilis. It is curious to reflect that, although Wagner-Jauregg began his therapeutic experiments in general paralysis so long ago as 1887, when he tried the effect of the inoculation of erysipelatous material, it was not apparently until thirty years later that he took up the problem again and this time solved it, as events have proved; for the whole outlook in the disease has changed, and, apart from technical improvements in treatment, further advance depends almost entirely on early diagnosis, and on social factors such as education. The success of a purely electrical method implies also a theoretical contribution, since evidently it is the pyrexial effect which is the therapeutic agent. Weichbrodt and Jahnel[3] had shown that in rabbits a temperature of 42° to 44° C. led to disappearance of the spirochaetes from the primary lesion, but this was not thought convincing, as such high temperatures were rarely if ever reached in malaria. In this connexion, however, not only is the therapeutic effect of diathermy noteworthy, but so also is the fact that the best results in the American series were obtained in cases in which the fever was highest (106° to 106.4° F.), although no better result was obtained by proceeding to still higher levels than this. It does not necessarily follow that the spirochaete cannot survive such temperatures *in vitro*; it is possible that the effect depends on hormonal alterations which make life impossible for the spirochaete in the body. That this may be the explanation is suggested by the observation that epilepsy, a purely neural process, may be improved after acute fevers. It is odd that no one seems to have followed this old scent in the case of epilepsy, as Wagner-Jauregg did so faithfully and persistently for general paralysis, transforming a prospect of ineluctable disaster into one of measured hope.

DURATION OF SECONDARY SCHOOL LIFE

One of the most important factors, if not the most important, affecting the efficiency of the entire system of secondary school education is that children should remain at school long enough to profit adequately by the facilities provided. In a recent paper Frank Sandon[1] presents data of the greatest interest on the methods of measurement of the duration of secondary school life, together with an analysis of some of the factors affecting it. He begins with a criticism of the statistical methods used by the Board of Education. These introduce anomalies into the measurements and ignore such factors as sex and the effect of transfer from school to school within the system. He proposes, instead, a system which is almost strictly analogous to the calculation and utilization of the ordinary actuarial life-tables. Thus it is possible to speak of "entrants" and "exitants" (instead of leavers), "survivors," "mortality," "expectation of life," and so forth, using these terms for the duration of secondary school life just as they are used in connexion with life-tables. Sandon applies his methods to data carefully collected from a single mixed secondary school over a period of ten years. The numbers, therefore, are not large, but even so the conclusions are of high interest.

In the case of the boys two outstanding factors affect the duration of secondary school life. One is social class; and in this connexion it is striking that a relatively slight improvement in socio-economic status results in a very considerable extension of school life. The second is the opportunity for employment. It was found that when conditions in the labour market were bad boys stayed on longer. When employment conditions improved parents tended to make sure as soon as they could of some sort of job for their sons—almost no matter what it was, as they often told the head master. Academic ability proved to be a minor influence. The brilliant certainly stay longer, and the dull have a shorter school life. Apart from these extremes, the less able stay longer at school. There seems to be a tendency to stay on in order to pass the School Certificate examination, but this is far weaker than the tendency to leave in order to secure employment. Age at entry is also a minor influence; not unexpectedly the younger entrants tend to have a longer school life. The results for girls are quite different from those for the boys. Girls have a shorter school life and tend to stay at school primarily for general educational purposes rather than as a preparation for the passing of particular examinations. The effect of economic pressure is less marked than in the case of boys. The author concludes that girls tend to stay on as long as they continue to make some headway with the work and for that period which local custom has established as conventional.

The data present an exceptional opportunity for the examination of one point. In 1936 it was decided to close the school in question at the end of the summer term of 1937, no new pupils being admitted after September, 1936; survivors in September, 1937, were to be transferred to other schools in the area. This provided an occasion for examining the effect of transfers. It was found that the effect among the boys was to increase the leavers by 50%. Among the girls the effect was even more disastrous. In view of recent recommendations, which if adopted would increase such transfers, it is clear that this point merits further and close research. The most signifi-

[1] *Ann. Eugenics*, 1940, 10, 253.

cant thing about the paper is not, however, the actual data it presents. It is an essay in method, and points the way to a more efficient system of collecting and analysing the mass of data available to large authorities. Research on these lines should prove a sound guide to our administrators who, Sandon suggests with some acidity, "at present seem to be guided by their prejudices, their impressions, and their reading of Quintilian."

MEDULLOTROPHIC AND PANCREOTROPHIC ACTIVITY

In the early part of last year Professor Collip of Montreal reported the demonstration of medullotrophic activity in a primary alcoholic extract of the anterior pituitary gland. This extract stimulated the "dark cells" of the adrenal medulla in the hypophysectomized rat.[1] More important, it dimipished the blood sugar and glycosuria in diabetic patients and produced hypoglycaemia in some normal animals. A unique property of the extract was that it was active when given by mouth. In the summary of his second paper[2] Professor Collip suggested that his extract exerted "a profound effect upon carbohydrate metabolism." Comment on these findings in this *Journal*[3] displayed interest tempered with a certain amount of scepticism, chiefly due to the fragmentary nature of the evidence provided in what it was assumed were merely preliminary notes. Further publications on the subject have not yet, however, reached this country, and the implied scepticism has obtained a more factual basis from the recent publication of two papers by Lawrence and Young[4] and by Marks and Young.[5] In the former paper the authors record their findings when alcoholic extracts of fresh ox anterior pituitary prepared according to the method of Collip[6] were given orally to four diabetic patients. No diminution of glucose excretion or of blood-sugar level was observed. The authors also found no demonstrable effect when the extracts were fed to or injected into "pituitary-diabetic" dogs. These are the dogs, first described by Young, which develop a permanent diabetes after massive injections of crude anterior pituitary extract. They are called "chiens de Young" in France, but in this country phonetic ambiguity deprives Dr. Young of the honour, already accorded to Professor Houssay, of having the preparation named after him.

Marks and Young[5] examine the claim of Collip that the alcoholic extract contains pancreotrophic activity. They performed their tests by giving the extract daily to a group of ten rats for fourteen days and subsequently estimating the insulin content of the pancreases of the treated animals. Collip's alcoholic extract did not increase the insulin content of the pancreas whether given by mouth or by injection. Other extracts of the anterior pituitary gland did, however, exhibit pancreotrophic activity and were investigated. The most important result of the experiments was in the distinguishing of the pancreotrophic activity from the activities of the anterior pituitary hormones. First, as oestrogens were known to have a pancreotrophic action, testosterone was injected, but had no effect on the insulin content of the pancreas. This fact, combined with the fact that castration had no influence on the pancreotrophic activity of the pituitary extracts, showed that the gonadotrophic factor of the pituitary was not responsible for the effect. Further proof of this distinction lies in the fact that gonadotrophically inactive preparations may have pancreotrophic activity. Similar facts differentiate the pancreotrophic effect from prolactin and from thyrotrophin. It is distinguished from the glycotrophic factor by virtue of its instability to heat. Species differences were found in the content of pituitary gland in pancreotrophic activity. These observations show that pituitary extracts do contain a distinct factor which raises the insulin content of the pancreas in the rat, but the authors are careful to emphasize that neither in their laboratory nor in that of Professor Best in Toronto, who is also working on this problem, has any evidence been brought forward to show that the factor plays any physiological part in the normal organism. It is not yet entitled to be called a hormone. Whether or not Professor Collip's extract is entitled even to be called a factor remains to be proved.

[Since the above note was written Prof. Collip has withdrawn his claims, describing their publication as a "serious error in judgment."[7]]

NEW F.R.S.s

The names of twenty new Fellows of the Royal Society were announced last week. They include Surgeon Rear-Admiral Sheldon F. Dudley, M.D., F.R.C.P., Medical Director-General of the Navy (designate); John Carew Eccles, M.B., F.R.A.C.P., Director of the Kanematsu Memorial Institute for Pathology, Sydney, formerly Fellow and Tutor of Magdalen College and University Demonstrator in Physiology at Oxford; H. W. Florey, Ph.D., M.B., Professor of Pathology at Oxford; Joseph Needham, Sc.D., Reader in Biochemistry at Cambridge; H. G. Thornton, head of the bacteriology department, Rothamsted Experimental Station; and P. Bruce White, B.Sc., of the department of experimental pathology and bacteriology at the National Institute for Medical Research, Hampstead. Admiral Dudley is at present medical officer in charge of the R.N. Hospital, Chatham; he was formerly director of medical studies and professor of hygiene and pathology at the Royal Naval College, Greenwich, and he has published many papers and reports on bacteriological and epidemiological subjects. Professor Florey (like Dr. Eccles) is a former Rhodes scholar from Australia, and he held the chair of pathology at Sheffield for four years before his return to Oxford. Dr. Needham was Oliver-Sharpey lecturer at the Royal College of Physicians, 1935–6, and is well known for his philosophical writings on embryology and biochemistry. Mr. Bruce White has made fundamental studies of the antigenic constituents of the different species or organisms belonging to the vibrio group.

Mr. L. R. Broster has received an invitation from the American Surgical Association to be their guest and speak at their annual meeting at White Sulphur Springs, Virginia. The Medical College of Virginia has also asked him to deliver the McGuire Foundation Address on his research work on the adrenal gland. These invitations are very welcome as expressing the sympathy that exists between the medical professions of the United States and the British Commonwealth, and as affording a British surgeon the opportunity to give his colleagues in the U.S.A. a first-hand account of our problems in this country.

We regret to announce the death at the age of 90 of Sir William Smyly, M.D., for many years one of the leading obstetricians and gynaecologists in Dublin. He was a past President of the Royal College of Physicians of Ireland and of the Leinster Branch of the British Medical Association.

LOCAL TREATMENT OF BURNS

E.M.S. MEMORANDUM

The notes on the local treatment of burns printed below are based on the recommendations of the co-ordinating team on burns appointed by the War Wounds Committee of the Medical Research Council. The full text of the memorandum has been circulated from the Ministry of Health for the guidance of medical officers in Emergency Medical Service hospitals and first-aid posts. It is designated E.M.S./Gen./343.

Treatment at the First-aid Post

Minor burns which do not require admission to hospital should, after cleansing the surface with plenty of soap and water, be dressed in the following way: (1) in the case of the face or hands, with gauze or lint impregnated with sterilized vaseline; (2) in other parts of the body, with tannic acid jelly or gentian violet jelly, 1%. If jellies are used no *dressing* should be applied over the burnt area, and clothing must not be allowed to come into contact with the burn area until the coagulum has formed and is dry. The application of tannic acid or other coagulant jelly to the surface of a burn which has not been adequately cleansed is inadvisable.

Serious burns requiring admission to hospital should be treated by the application of sterile vaseline[1] on gauze or lint to cover the exposed portions of the burn. Provided the patient is shortly to be transferred to a near-by hospital, no attempt should be made to remove clothing in order to expose the entire burn area. Serious burns always require injections of morphine for pain, in full doses (1/3 to 1 2 grain for adults).

Local Treatment in Hospital

At the first hospital, where the case can be fully treated, the following lines of local treatment are advised for extensive burns of whatever degree.

Under gas-and-oxygen or pentothal anaesthesia, the burn areas should be thoroughly cleansed by the gentle but liberal use of soap and water, followed by saline and by the removal of debris under strict aseptic precautions (soft soap should not be used; the best application is some form of soap flakes). No violent scrubbing or scraping should be used, nor should antiseptic solutions or spirit be employed. If the burn area is impregnated with oil or grease, ether soap is of value for cleansing. *Extensive burns should never be fully exposed at one time*, owing to the risk of increasing shock by loss of body heat: a limited area only should be exposed for treatment, which should be completed before the next area is dealt with. *Loss of heat is especially marked when ether soap is used.* After the cleansing process has been completed, the burn surface and the skin around should be dried and the burn surface should be lightly dusted with sulphanilamide powder: a coagulant is then applied, except on the face, hands and wrists, and feet.

Coagulant Applications

The following solutions are the most suitable, as they act quickly and require no special apparatus, etc.:

1. Silver nitrate, 10%.
2. Tannic acid, 10%.
3. Silver nitrate, 10%, and tannic acid, 5%, used alternately.
4. "Triple dye." (One formula in common use is gentian violet, 1 in 400; brilliant green, 1 in 400; with neutral acriflavine, 1 in 1,000. The solutions are mixed in equal proportions.)

The application is best made by the use of a large gauze mop; no dressings are required over the coagulated area, but it is advisable to cover the part with a sterile towel after the coagulum is dry. The edges of the area and any cracks that may develop on the surface should be dusted daily with sulphanilamide powder. In whatever way coagulation is effected the coagulum must cover the whole area and a good margin of unaffected skin around, and must be firm and dry, or else the effect of the treatment is lost as the patient will still lose fluid from the burn area.

The areas in which no coagulant of any kind should be used are the face, the hands and wrists, and the feet. In addition to the solutions given above, tannic acid jelly and gentian violet jelly are coagulants. Circumferential tanning of a limb should be avoided if possible, and if carried out the peripheral pulse must be carefully watched for the first forty-eight hours. Coagulants tend to contract on drying, and there is a risk of dangerous constriction of vessels or distortion of tissues—for example, the fingers and eyelids—as this occurs.

Treatment of Burns in Areas which should not be Tanned

After cleansing the burn area in the manner described above, the surface is dried and dusted with sulphanilamide powder. A "tulle gras" dressing[2] is then applied, and this in turn is covered by six to eight layers of gauze wrung out in warm normal saline. The gauze must be kept moist by warm saline being dripped on it from time to time, and on no account must it be allowed to become dry. The tulle gras will enable the gauze dressings to be removed without causing pain or injury to the burn surface, provided they are kept moist; as a rule it is advisable for the first few days to change the gauze every three to four hours, the tulle gras being left undisturbed during this process. Twice a day at first, and subsequently according to the progress of the case, the tulle gras dressing is changed: where it is possible to immerse the affected part in a bath the tulle gras dressing is allowed to float off, which it does readily. In the case of the face or other parts for which a bath cannot be used, a gentle stream of saline greatly assists in the removal, which should be painless and not associated with bleeding. Where baths are used the limb can remain immersed for half an hour or more, the saline being kept warm throughout. Before applying a fresh dressing the unburned surface of the limb is dried and the burn area dusted with sulphanilamide powder.

Dressings must be carried out with full aseptic technique, and special care must be taken to ensure the surgical cleanliness of the arm and leg baths. An oil silk or jaconet bag or cover is of value in keeping the gauze moist in the case of the arms and legs, both while the patient is in bed and during transport. Where burns of the face are treated by saline packs a jaconet bib assists in keeping the patient and the bed dry.

All cases of severe burns likely to be followed by loss of function or disfigurement, or to require extensive grafting, should be transferred to a burn centre as soon as they are fit to travel.

[The memorandum concludes with detailed directions for preparing sterilized vaseline dressings, and "tulle gras," and the jaconet bib.]

[1] It is hoped that in the near future a non-greasy substitute will be available for use instead of vaseline.

[2] Tulle gras may be prepared in the following way: Curtain net with a mesh of 2 mm. is cut into pieces 9 cm. square: these are placed in a tin box of slightly larger size, and the box is filled with a mixture of soft paraffin 56 grammes and balsam of Peru 2 grammes, sufficient to impregnate and cover the material completely after sterilization by heat in an autoclave.

The annual report of the Ling Physical Education Association shows an increase of membership and continued activity. There is little unemployment in the profession: on the contrary, many new opportunities for teachers of physical training are available. The work of members in educational and recreative physical training in reception and evacuation areas, in the Services, and in social welfare shows the value of the training in the physical training colleges and the importance attached to physical education in wartime as in peace. Among the association's publications, the pamphlet "Ventilation in Blacked-out Halls" has been in great demand. A special panel is now engaged in compiling "A Modern Approach to Health Education," to be published by the University of London Press. The report states that last year a resolution was forwarded to the Board of Education by the Ling Physical Education Association Committee recommending that more attention be paid to the teaching of hygiene in schools. The resolution was supported by the British Medical Association, the Association of Headmistresses, the National Council of Women, and the Federation of Women's Institutes.

Reports of Societies

PROBLEMS OF WAR CASUALTIES

At a meeting of the Liverpool Medical Institution on March 6, with the President, Prof. O. HERBERT WILLIAMS, in the chair, Dr. WILLIAM JOHNSON and Prof. T. P. MCMURRAY opened a discussion on major medical and surgical problems of war casualties.

War Neuroses

In opening the discussion on war neuroses, Dr. Johnson remarked that in anticipation of cases occurring among civilians as a result of air raids an E.M.S. Centre was opened early on in the present war. A scheme was drawn up, and instructions were circulated by Mr. Monsarrat, Group Officer, to first-aid posts and receiving hospitals, with suggestions for dealing with patients in order to limit the number admitted to the centre. But experience in this area had shown a dearth of civilian cases, and not a single one had been admitted to the centre. This experience was very similar to that in other centres. After the evacuation of Dunkirk a group of patients was admitted comprising types similar to those admitted to a centre in France during the battle of Passchendaele. The majority of cases, however, admitted to the centre in the past eighteen months were soldiers who had not served outside this country. Some were Army misfits, others needed grading into lower categories, and some after treatment were fit to return to their units. With regard to the latter a follow-up system was being carried out. Those whom it was found necessary to board out of the Army were chiefly among the misfits and men who had suffered from neuroses in civil life.

In regard to treatment the hospital atmosphere was so far as possible excluded. Very few patients were kept in bed, and a routine programme was in operation which ensured that patients were occupied through the day. Physical training instructors, occupational therapists, and instructors from N.C.O. patients had been appointed. Carpentry, basket work, raffia work, weaving, squad drill, route marches, games, and talks on military subjects were part of the programme.

Dr. F. HOPKINS referred to the controversy in the medical press some months ago on the subject of treatment at "neurosis centres," the point at issue being whether patients should have the benefit of the highly specialized forms of treatment of modern medical psychology or whether the archaic "neurological" methods in use before the last war should still be followed. The real issue in this discussion was whether patients as a whole should be treated from the standpoint of one particular school of medical psychology—namely, the psycho-analytic—or whether they should be dealt with by more flexible and practical methods of applied psychology. While the choice and carrying out of psychological treatment was important, it formed but one of the functions of the psychiatrist, and the task of diagnosis, prognosis, and disposal was equally important, only a relatively small proportion of patients requiring or being able to benefit by anything other than the more superficial kinds of treatment. A most difficult problem was that of the disposal of the man who, though his disability might be slight, was unlikely to be a satisfactory soldier on account of personality type and attitude to service, but who might be an adequate civilian worker.

Dr. S. BARTON HALL directed his remarks to two main questions—namely, neurosis in the Army as compared with that encountered in the civilian population, and the continued admission of mentally defective persons into the Army. With regard to the former, he considered it important to determine as early as possible the man's fundamental attitude towards service as distinct from that outwardly expressed, as thereby much unnecessary effort, waste of therapeutic skill, inefficient service, friction in the military machine, not to speak of expenditure of public money, might be saved. In a series of 150 consecutive cases investigated, few of which were acute, the attitude towards service was at the outset found to be unsatisfactory in approximately half (76). Of these, only two men could be rehabilitated to a degree sufficient to enable their return to their unit. On the other hand, of twenty-four patients in whom attitude towards service was found to be satisfactory, twenty-one returned to their unit with, it was felt, in many cases an excellent prospect of rendering further useful work. Dr. Barton Hall commented on the proportion among those whose attitude was unsatisfactory of men, often over the age of 40, who had previously served in the Army and, in a number of cases, had even been invalided out and pensioned during the war of 1914–18.

Of thirty-three soldiers referred for psychiatric investigation as out-patients eleven were found to be mentally defective, though previously unascertained, and in two more intellectual development was found to be so retarded as to incapacitate them for military training or service in any grade. The anomaly in the examination of recruits thus revealed was a matter of concern for the Army, and indicated a defect in the application of provisions for ascertainment of mental defect in the Education and Mental Deficiency Acts, and also in the system of medical education whereby a Board of medical men could pass individuals so handicapped as suitable for military service.

Dr. N. S. ALCOCK said that the essential in running a war neurosis centre was the combination of physical and mental management. In dealing with the purely physical handling of cases the initial interview of every patient on admission was most important. In this, the attitude of the patient was determined: first, whether he was a man who should or should not be allowed to mix with the other men in the centre; or whether, as in hysterical patients, symptoms must be removed before the man could join in the centre. Secondly, the question of occupation was discussed, both as to what the man could do to help in the occupational programme and what type of occupation would most benefit him. Lastly, he was allocated to his medical officer. Unless there was a fairly close approximation between the life in the centre and the life in the Army, the adaptation the men made in the centre might be of little help when they returned to their Army life.

War Surgery

In opening the discussion on surgical problems Prof. T. P. MCMURRAY said that the outstanding feature of the surgery of the present war, as compared with that of the last, was the almost complete disappearance of the ward dressing trolley and the ward gas apparatus. The appalling pain caused by the daily, or twice daily, dressings had gone, and in its place was the modern technique of excision and fixation. Fixation was practically always by plaster-of-Paris, although in the wounds of the thigh in fat women complete fixation by this means was an extreme difficulty. An addition to the technique was the use of sulphanilamide by packs or in powdered form, or by insufflation on the surface of the wound; although the use of sulphanilamide had helped to prevent sepsis in some cases which had not come for operation for four to eight hours after the infliction of the wound, nothing could replace the perfect excision of the wound, which was the essential point in the treatment. Nothing was so criminal as to suggest that the excision could be done badly so long as sulphanilamide was used. The main problems met with now were shock, for which fortunately the treatment was almost standardized; the prevention of sepsis, which depended largely on the excision of infected and dead tissues and the wide opening-up of tissues which had become infected; and fractures of the pelvis, which had occurred more frequently than normal owing to the falling in of bombed houses. In many of these cases of fractured pelvis there was a rupture of the urethra, and it would be well if agreement could be reached on the ideal treatment of this complication. Were the patients with a ruptured urethra to be treated with a catheter in position, or were they to be treated by suprapubic cystotomy; and what were the advantages of each?

A warning should also be given to those who without experience used plaster-of-Paris. This was a safe method of treatment so long as it was applied smoothly and without pressure, but if skin-tight plaster was applied on a limb, then the patient should not be transferred from the hospital for at least forty-eight hours. During that time any abnormal

point of pressure could be diagnosed and the pressure relieved, but if the patient was allowed to leave and go home or to another hospital soon after the application of the plaster, tragedies might happen.

The PRESIDENT said that in considering rupture of the urethra it was necessary to differentiate between the intrapelvic and extrapelvic varieties. In the former the urine escaped into the pelvic cellular tissue behind the triangular ligament; whereas in the latter the escape was into the tissue of the perineum in front of the triangular ligament. It was the intrapelvic variety that occurred usually in cases of fractured pelvis. To establish the diagnosis of such a rupture it would be necessary to pass a catheter. This should be done with the greatest care and gentleness, for more likely than not the tip of the instrument would pass through the rupture into the pelvic cellular tissue—this would tend to spread infection. Even if the catheter did pass beyond the rupture into the bladder drainage would be inadequate; urine could still pass along the outside of the catheter and further infect the periurethral tissue. In view of these considerations, therefore, it would appear that immediate suprapubic cystotomy and suction drainage was the rational line of treatment to follow in these cases.

The speaker differed from Prof. McMurray when he placed bipp in the same category as the sulphonamides in the treatment of wounds. Bipp was an antiseptic—a protoplasmic poison—and therefore had no place in the treatment of fresh wounds. The sulphonamides, on the other hand, were not protoplasmic poisons. Recent work showed that these drugs could be inserted into the tissue and even into the peritoneal cavity without causing any appreciable tissue reaction: even skin grafts would grow on a surface that had been sprinkled with sulphonamides. Their role was purely bacteriostatic, and they did not interfere with the natural defensive tissue reaction.

Mr. F. RONALD EDWARDS said that in many cases plasma was still not being used in sufficient quantities, and a rapid increase in the blood volume was necessary in some severe cases of shock. This could only be obtained by forced plasma administration with multiple cannulae. Oxygen therapy by the B.L.B. mask in shock was sadly neglected, and this addition might turn the tables in a desperate case. The use of desoxycorticosterone should be given a fuller clinical trial in shock. There appeared to be considerable difference of opinion as to how and when to give sulphonamides in cases of war injuries. There were certain wounds which could not be satisfactorily excised without producing a deformity out of all proportion to the original injury. Many wounds came into close relation to important vessels and nerves which could not be excised and which were still potentially infected. There appeared to be a definite inhibitory effect on anaerobic infection, and for these reasons sulphonamides should be inserted into the primarily excised wound. With already grossly infected wounds sulphanilamide placed in the wound would tend to be washed away by the discharge, and it was better to administer it by mouth or intramuscularly, so that the organisms deep in the wounded area would receive the drug via the blood stream. If possible, estimation of the concentration in the blood should be done, a value of 10 to 15 mg. per 100 c.cm. being maintained. The incidence of gas gangrene was low—0.5% in the area, with a mortality rate of 40%. Tetanus had not been seen.

Concerning perforating abdominal wounds, patients with involvement of solid viscera only as a whole did well, but in patients with perforation of the alimentary canal there was a mortality rate of over 90% in those submitted to operation. These patients died from shock, not peritoneal infection, and much further work was needed to investigate the action of sulphonamides in the peritoneal cavity to stay infection, so that if possible the shocked state might be more efficiently treated before these people were operated on.

Miss Anna Freud, daughter of the late Prof. Freud, has opened a clinic in Hampstead for mothers and babies who are suffering in mind and body from air raids. Treatment is free and patients are kept at the clinic until they are cured. A doctor is in attendance night and day, and there is a staff of trained nurses.

Correspondence

Crush Injuries

SIR,—The accounts of the crush injuries with renal failure (March 22) indicate that want of oxygen is an important factor, and that the inhalation of oxygen should be a method of treatment, this to be given, if possible, before release from confinement by debris, as well as after. Radiant heat given by means of a cradle and incandescent lamps should, I think, also be given. The circulation of the blood is kept up not only by the force of the heart, but by the tone not only of the muscles but of all the living cells, which, confined by skin and membranes, support the capillaries by their normal turgescence. Hence the firmness of the healthy body, which is diminished or lost in shock. Every muscular movement and change of posture furthers the circulation, and these effects are lost by fixation of the body under debris, while by pressure some parts may be rendered bloodless. Oxygen inhalation will lessen the damage caused by the deficient circulation.—I am, etc.,

St. John Clinic, S.W.1, March 23. LEONARD HILL.

SIR,—The series of cases of crush injuries with impaired renal function reported in the *Journal* of March 22 calls for comment in relation to the nursing of the severely injured.

Crush injuries are not new. They are commonly seen on the coalfield, where the treatment is careful nursing and non-interference rather than physiological and biochemical assay.

The case of fatal uraemia in a girl of 11 years reported by Mayon-White and Solandt suggests nephritis. The other cases from the Postgraduate School suggest a syndrome which might be dubbed the "continuous interference syndrome." Not only had the patients been subjected to readings of pulse, diastolic and systolic blood pressure, estimations of haemoglobin, oscillometric readings of leg volume in already injured right and left legs, radiographic examination, electrocardiographic examination, but even to catheterization—which in itself may give rise to shock. The repeated examinations for so-called blood chemistry and urine chemistry give a picture of the extent to which rest was allowed to figure in the treatment. The main objection, however, is to the volumes of fluid injected either in the form of blood, serum, plasma, or normal glucose-saline. In several cases the volume injected was equal to the blood volume of the patient. In one case 100 c.cm. of 30% saline was injected; in another 400 c.cm. of serum of quadruple strength. The patient complaining of thirst was given 200 c.cm. of 50% sucrose. Another, with an increasing chloride content, was subject to drastic reduction of chlorides by sweating, purgation, and replacement of gastric juice by sodium bicarbonate.

Haemorrhages in the newborn are frequent, either subtentorial, post-hepatic, or suprarenal. The haemorrhage under the scalp associated with caput succedaneum is almost a normal feature of childbirth. Most of these cases do well with peace, quiet, rest, and non-interference. The jaundice and occasional uric acid infarct of the kidney clear up. The uric acid infarct is rarely seen post mortem in the case of the stillborn, but is seen frequently in the case of the babe who succumbs soon after birth in the neonatal period.

Might I suggest that the system which works for haemorrhage and shock in the newborn be tried for traumatic shock? At birth the mammal has learnt to survive a series of shocks which involve the circulation, the respiratory system, the urogenital system, and the skin. We require not only charts of blood chemistry and urine analysis, but something which will be as effective to the injured as colostrum is to the newborn mammal. "Poor Tom's a-cold."—I am, etc.,

H. A. HARRIS.
Professor of Anatomy.

University of Cambridge, March 24.

SIR,—The interesting observations of Drs. Bywaters and Beall on cases of renal failure following prolonged burial under debris raise two points of interest and minor criticism.

First, as the surgeons in charge of the cases cited, we feel that the characteristic clinical picture has not been sufficiently emphasized. These cases on admission did not suggest grave

surgical emergencies. On the contrary, the primary injuries usually appeared trifling, the wheals, oedema, and interference with the local arterial circulation being the only gross signs of the ordeal to which the patients had been subjected. This absence of gross trauma, as pointed out in a previous letter to your *Journal* (September 28, 1940, p. 432), led the surgeon to feel that the cases would probably have a favourable outcome. Within a few hours, however, the whole clinical picture had changed dramatically. Signs of peripheral circulatory failure rapidly appeared, with pallor, sweating, and coldness of the extremities. Coincidently the blood pressure fell, and haemoconcentration was noted. At this stage the picture was one of traumatic shock, and when a good response followed transfusion the surgeon was again tempted to feel that the outlook was good. The response was, however, only temporary, and the sign that we soon learned to dread made its appearance—namely, a steadily progressing oliguria. Thereafter the clinical picture resembled in many respects that seen in renal failure in prostatic enlargement, and has proved, up to the present, as difficult to treat.

These three phases—a comparatively good condition on admission, a delayed peripheral circulatory failure which responds to transfusion, and finally progressive renal failure—make up a typical clinical picture which should be widely known.

Secondly, the use of the word "crush" is not in our submission desirable—suggesting as it does massive destruction of bone and muscle such as is seen in industrial accidents. In effect, in the severe crushing injuries, such as multiple compound fractures, which we have dealt with in this hospital we have not seen a case of renal failure. On the other hand, common to all the cases which developed renal failure in our series was a history of having been pinned for a prolonged period under debris. We therefore feel that the *duration* of the trauma is of great importance, and that probably ischaemia of the tissues distal to or immediately beneath the point of pressure by the debris is a contributing factor in the later developments. We would therefore suggest some such term as "pressure ischaemia" or "compression syndrome" as more suitable.—We are, etc.,

Cysticercal Epilepsy

SIR,—The case of cysticercal epilepsy reported by Dr. William Blyth in your issue of March 15 (p. 401) illustrates the importance of considering cysticercosis as a possible cause of epileptiform attacks commencing in a previously healthy adult after service or residence abroad. Unfortunately, however, there is at present no certain method of excluding this disease during life. The brain may be invaded, and the musculature remain free; and since intracerebral cysts usually do not calcify, radiographic examination of such cases is likely to be negative. Even when the muscles are invaded, the parasites may lodge too deeply for detection; or if very few in number none may happen to calcify, for all cysts do not go on to ultimate calcification.

Ideally every subject under suspicion should be examined each year, but this is a laborious and costly business, wearing to the patience of all parties. When such a procedure is possible, however, the longer the period during which re-examinations are carried out the more likely is a positive diagnosis to be forthcoming. A cyst which is flaccid and impalpable while the parasite is alive may become tense and swollen after its death, and so be easily perceptible to touch and possibly to sight. In one man whose symptoms of major epilepsy began in this country a year after leaving the Army, a cyst of this type appeared ten years after the onset of his symptoms. It was so obvious that no one could miss it. I had examined him carefully on at least twelve previous occasions over a period of years without detecting anything in the area affected. Another man who had been examined radiologically from head to foot no fewer than seven times over a period of ten years without result showed two calcifying cysts in the twelfth year of his disease. Nevertheless, whatever the duration of observation a large proportion of suspects will remain undiagnosed, although their history and symptoms are identical with those of others in the positive group, and a definite decision, one way or the other, can be obtained only by a post-mortem examination of the brain. Lately two men who had been examined for cysticercosis with negative findings came to post-mortem examination, not as the result of a follow-up—always difficult to ensure—but because death had resulted from other than natural causes. Both showed cysticerci in the brain; none was found elsewhere in the body. Again, fits may be attributed to some other cause on what seems good evidence. One man with an authenticated history of head injury while in the Army was investigated in a civil hospital by encephalography and other scientific measures. A firm diagnosis of traumatic epilepsy was made. These examinations, however, failed to disclose the presence of the fifty cysticerci which were counted post mortem in his brain four years later.

The following case history points the moral of my opening sentence. In May, 1936, when I was Commandant of the R.A.M. College, an ex-soldier clerk, employed in the library, asked to see me and told this story. The previous evening in a public-house he got into conversation with the bartender, and learned that he was an ex-soldier and had suffered from epilepsy for about six years past. The attacks had begun after he left the Army. He was undergoing a course of sedative treatment prescribed in the neurological department of a London hospital. The clerk asked if he had ever noticed any little lumps under his skin. The man replied: "Yes, I have three or four now." "Well," said the clerk, "you haven't got epilepsy at all; you've got cysticercosis." I examined the man a few days later and confirmed this spot diagnosis. I learned that besides attending the hospital mentioned he had been in the care of several doctors, and had also been in the wards of another London teaching hospital, where he was brought by ambulance, having been picked up in the street unconscious after a fit. According to the man's statement, the "little lumps" had been present during all this time. The ex-soldier clerk thought of cysticercosis; the professional practitioners did not. "*Ex ore infantium et lactantium* . . ."!—I am, etc.,

W. P. MACARTHUR.

London, March 20.

Treatment of Rectal Carcinoma

SIR,—There are a number of points raised in Dr. Ff. Roberts's article on the *x*-ray treatment of inoperable carcinoma of the rectum without colostomy (March 8, p. 357) which require discussion. While recognizing that exceptions occur in cases of high-grade malignancy and in cases of early venous spread, I agree with his statement of the slow rate of growth in rectal cancer, and the absence of distant metastases until a late stage of the disease has been reached. It is for these reasons that *a high proportion are found to be operable* when they are approached surgically (that is, explored) under the best conditions of team-work and pre- and post-operative management. For instance, out of 104 new cases of rectal cancer admitted into St. Mark's Hospital during 1940, 76, or 73.1%, were locally operable, although three of these cases were found to have small secondary deposits in the liver at the time of operation.

It would be pertinent to inquire by what standards Dr. Roberts judged his cases to be inoperable. My own experience is that one rarely meets with a case which is frankly inoperable locally in which distant metastases have not taken place. A good proportion of those which are classified on a clinical basis as of border-line operability prove on abdominal exploration to be operable, especially in male subjects. If laparotomy is denied to these cases many potentially operable cases will be missed.

If the discussion is limited to the large inoperable carcinomas of the *rectal ampulla* in which discharge is profuse and obstruction absent, then I would agree that there is a fair reason for giving *x*-ray therapy without colostomy unless some local complication such as a recto-vaginal fistula has developed. About 70% of cases occur, however, in the *upper* third of the rectum, where obstructive symptoms are likely to be prominent and important. A laparotomy is the only method of determining whether such cases are operable or not; if inoperable, I think a colostomy is the right treatment, which can be supplemented later by intraluminary radium or by *x* rays.

A new source of Vitamin C for Infants

At a time when supplies of fresh fruit juice may be uncertain for an indefinite period, the provision of an alternative source of vitamin C is imperative. *Infant* Celin, the new Glaxo preparation of vitamin C, is introduced for this purpose. Each *Infant* Celin tablet contains 5 mg. ascorbic acid, approximating to 2 teaspoonfuls of orange juice. During the second month and onwards, one tablet should be given daily, dissolved in the bottle feed, or, for breast-fed babies, in a little boiled milk or water. From four months onwards, the daily ration is two tablets. It is pertinent to mention that (a) the anti-scorbutic properties of *Infant* Celin are not affected by giving the tablets in warm milk, water or milk-feed; (b) the tablets dissolve readily in milk, which is not curdled thereby; (c) no digestive upset is caused.

During the first two months of breast-feeding, vitamin C is rationally taken by the mother. For this purpose, and also to guard against the possibility of vitamin C deficiency in the war-time diets of other adults and of the older children, the larger Celin Tablet (50 mg. ascorbic acid) is recommended. Separate literature is available on request.

INFANT CELIN

PRODUCT OF THE GLAXO LABORATORIES

Bottles of 50, 1/3; 1000, 12/-. Subject to usual trade discount and to purchase tax.

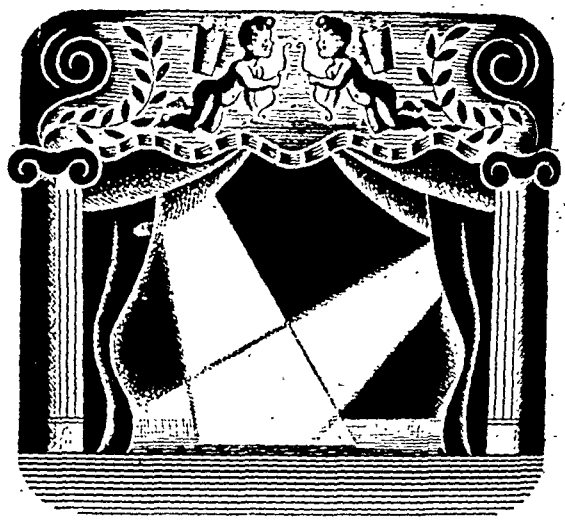
To secure protective reserves

in ADOLESCENCE, PREGNANCY and DEBILITY

There are always among your patients many whose greatest need is simply more iron, calcium and vitamin D. To-day's food restrictions virtually preclude an extra supply of these nutritional factors by dietetic means. Caldeferrum tablets, presenting iron, calcium and vitamin D in stated amounts, give the physician a simple means of restoring and maintaining the necessary reserves by exact and regular dosage and (often an important consideration) at small expense. Indicated particularly in pregnancy, lactation, and adolescence, the ★ routine of 4 Caldeferrum Tablets a day supplies the additional intake required to guard against increased drain on the body's store. The chocolate coating of the tablets makes Caldeferrum acceptable to all patients.



★ The routine of 4 tablets supplies exsiccated ferrous sulphate 25 mg.; calcium phosphate, 0·6 gm.; vitamin D, 2,000 I.U.

CALDEFERRUM

Iron : Calcium : Vitamin D in chocolate-coated TABLETS

Bottles of 50, 100, 300 and 1 000

'enter a doctor'

(MACBETH, ACT IV, SCENE III)

What is "a doctor"? Can the different personalities, interests and opinions which go to make the medical profession be harmonised and represented by a type? Lacking the courage of Shakespeare we leave our stage empty. We do, however, believe that the following statements are true of any doctor engaged in general practice:

(1) He likes to be able to depend on the safety and efficiency of the drugs he prescribes—and he can do so by specifying May & Baker preparations.

(2) He has cases every day in his practice which would benefit from one or other of the drugs listed below:—

* **DAGENAN—M & B 693** * *For pneumococcal, gonococcal, and meningococcal infections.*

* **THIAZAMIDE** *For cases which prove intolerant to* **M & B 693.**

* **SOLUSEPTASINE** *For parenteral administration in streptococcal infections.*

* **SONERYL** *For insomnia.*

* **GARDENAL** *For epilepsy.*

* **PROSEPTASINE** *For oral administration in streptococcal infections.*

* **SOLUSEPTASINE OINTMENT** *For topical application in bacterial skin infections.*

* **SONALGIN** *For insomnia associated with pain.*

* **RUTONAL** *For epilepsy.*

* **MYOCRISIN** *For rheumatoid arthritis.*

* **THEOGARDENAL** *For high blood pressure.*

* **S.V.C.** *For Trichomonal vaginitis.*

*TRADE MARK

By prescribing original containers whenever possible wastage due to repacking is prevented, thus serving the interest of National economy.

PHARMACEUTICAL SPECIALITIES (MAY & BAKER) LTD., DAGENHAM

if thought advisable. For inoperable carcinoma of the *lower* rectum involving the anal canal a colostomy is surely a desirable and necessary palliative operation for minimizing anal pain, and for relief of difficulty in defaecation or faecal incontinence.

As regards operative mortality, Dr. Roberts quotes from the paper which I wrote jointly with my colleague Mr. O. V. Lloyd-Davies in 1935 on a series of cases admitted to St. Mark's Hospital during the preceding twenty-four years. A mortality of 13.4% in 500 palliative colostomies was reported, but the post-script showed that by improved methods of anaesthesia and technique the mortality could be lowered to 5% (in forty-one operations). This figure has since then been almost maintained: during the last five years out of 201 colostomy operations for inoperable rectal cancer there have been 12 deaths (6%). Most of these deaths occurred in aged subjects, many of whom had intestinal obstruction, and were due principally to cardiac failure, uraemia, and coronary or cerebral thrombosis.

The four case reports given by Dr. Roberts are extremely interesting. To complete them one would welcome some information as to the results of abdominal examination and of digital and sigmoidoscopic examination of the rectum at the present time. Was a biopsy done originally? It would be instructive to know which grade of carcinoma has responded best to the technique employed.—I am, etc.,

London, W.1, March 25. W. B. GABRIEL.

Clinical Cancer Research

SIR,—In commenting on the annual report of the British Empire Cancer Campaign in your issue of March 1 (p. 329) you remark that in the report of the Clinical Cancer Research Committee there is no indication of the survival time of 2,915 cases living, out of 7,872 cases registered in 1938. We regret that no indication was given in the heading of this table that the figures represent the number of patients still living one year from the date of commencing treatment, or being seen at hospital in the case of those not treated. The average survival time of cases fatal within one year or less has been worked out separately for each region of the body; the present report includes that for the breast cases (45.8 months). This survival time will be worked out year by year, and it is hoped, when sufficient time has elapsed, to use it as a check on the results of treatment. Shortage of paper has not only prevented the publication of the figures for other regions, but has also necessitated the omission of a description of the method of coding and tabulation in these successive annual reports, though we recognize that it is desirable that readers in search of this information should not have to refer to previous reports.—We are, etc.,

Clinical Cancer Research Committee,
March 19. British Empire Cancer Campaign.

Resuscitation after Wound Shock

SIR,—The resuscitation of patients suffering from the severe degree of wound shock encountered in air-raid casualties has rightly invoked much discussion. The solution of the problem is considerably hastened by the publication of individual experiences such as those of Dr. Margaret Ball and Mr. George Quist (February 22, p. 273). These writers summarize their conclusions under five headings. Most of us will agree with their observations on the misuse of tourniquets, the economy of radiography, the necessity for the thorough excision of wounds, the adoption of a closed-plaster technique, and, finally, the ever-present danger of gas gangrene. On the other hand, the conclusion that the results of treatment of severe shock in these cases by fluid replacement with blood or plasma were disappointing is open to criticism.

In the first series of cases it is noted that most of the injuries were due to the direct action of the explosive. Here perhaps is a partial explanation for the failure to resuscitate these patients. Is it not likely that at necropsy these individuals would have shown lesions in the lungs and central nervous system which might account for the progressive deterioration despite the usual measures? I am presuming that necropsies were not done, as such are not recorded in the article. The rather pessimistic findings of the writers have not been supported by others in apparently similar series of cases. I do not suggest that the writers have implied that they are going to give up the use of blood or plasma in the very grave case, but I do consider that their observations might prove discouraging to others.

In the stress of air raids and the probable disorganization in hospitals it may not be easy to have necropsies performed. There must be, however, some opportunity to perform them in the type of case where there is no response to active resuscitation but where the local apparent injury does not seem too severe to obviate recovery. A plea is therefore advanced for early reports of complete post-mortem findings in the latter group of cases. Until these are available it will continue to be difficult to assess clinically the general visceral trauma present and so give "an accurate prognosis as regards immediate mortality."

I would be interested to know if lung changes, demonstrable radiologically, can be observed in the first hour or so after injury. If so, would these chest lesions provide a prognostic guide as to the central nervous system and other general lesions of blast? Limitations of the supply of blood, serum, or plasma demand that some real attempt should be made to define the "hopeless case"—if such exists!—I am, etc.,

JOHN A. SHEPHERD,
March 6. Surg. Lieut.-Commander, R.N.V.R.

Cut Tendons

SIR,—In connexion with Mr. H. Blacow Yates's letter (March 15, p. 417) I would suggest that before the finger which had its flexor tendons cut is, as a routine measure, thrown to the dogs, a thorough attempt should be made to restore function of the sutured tendons by the use of "amnioplastin," which, so far as I am aware, has not been given a fair trial in this kind of surgery.—I am, etc.,

Huddersfield, March 21. P. KOHNSTAMM.

Control of Catarrhal Infections

SIR,—The article by Surgeon Lieutenant R. Ernest King, R.N.V.R. (February 1, p. 154) prompts me to record a similar experiment which has been carried out during the present winter on board one of H.M. ships.

In November, 1940, coinciding with the return of a number of the ship's company from leave, several ratings reported with symptoms of the "common cold"—that is, slight sore throat, headache, and coryza, with little or no constitutional disturbance. As the first cases to report were confined to ratings from two mess-decks it was decided to attempt to limit the spread of infection among the rest of the ship's company by means of routine throat sprays and gargles. The ratings placed under observation were selected according to their disposition into different messes, so that each treated group was adjacent to an untreated group and shared the same living and working spaces, eight messes being chosen for this purpose. The numbers of the ratings in separate groups were unequal owing to the variation in size of the different messes.

The two messes already infected, together with two so far uninfected messes, were used as controls and received no treatment. Four other uninfected messes were selected for treatment, and the ratings were instructed to report to the sick bay every morning and evening on going off watch. Two of the latter groups were given gargles of pot. chlor. and ac. carbolic., one group received a throat spray of 10% potassium chlorate solution, while the fourth group was given a throat spray of 1 in 10,000 potassium permanganate solution. The members of all eight groups were instructed to report as soon as any symptoms of a sore throat or "common cold" made their appearance. This routine has been carried out for eleven weeks, and the following results have so far been obtained:

	Treated	Untreated
Total number under observation	36	58
Cases on sick list	0	2 (3.4%)
Cases on attending list	4 (11%)	12 (20%)

The sick list cases consisted of one "common cold" with frontal sinusitis, and one case of streptococcal tonsillitis. All

cases treated on the attending list were of the "common cold" type, beginning with dryness or soreness of the throat, followed by coryza and slight cough, with little or no rise of temperature. The four cases which occurred in the treated group had been treated with gargles only. No cases have so far occurred among those who have received the throat sprays.

This small series of cases indicates that a simple routine throat spray may be of value as a prophylactic measure against the normal winter incidence of upper respiratory infections, since it has been carried out during a period in which there has been no evidence of any widespread epidemic of these infections. Surgeon Lieutenant King's experiment has shown the undoubted value of such treatment in limiting the incidence of infection during the type of epidemic experienced in 1939–40.

This type of epidemic occurring in a closed community of relatively constant population, such as the complement of a warship, should be readily limited by routine prophylactic treatment combined with the prompt treatment of all cases showing even the mildest symptoms. A special look-out must be kept for such cases among newly joined personnel and in personnel returning from leave, in order to minimize the possibility of fresh infection. It has been noted during the past nine months that sporadic cases of throat infection have invariably occurred in ratings just returned from leave. Since leave is necessarily very limited under present conditions, the problem of fresh infection is somewhat minimized in a sea-going ship. This must, however, be a major problem in training establishments where there is a large moving population with a constant stream of new entries from different parts of the country, all of whom may be accompanied by their own varieties of viruses and cocci. The effects of this were seen during the "acute sore throat" epidemic of 1939–40, when a sharp rise in the number of cases admitted to hospital from shore establishments invariably coincided with week-end or other changes in the population.

The prevention and control of epidemics in the fighting Services appear simple in comparison with the problem as it affects the civilian population, so many of whom are now spending part of their lives in crowded air-raid shelters. The problems and peculiarities of the "shelter herd" have recently been summarized by Dr. W. H. Bradley.[1] In this article it is pointed out that many large shelters have developed a fairly constant population, the occupants of any one shelter tending to come from the same social, racial, or economic groups, with very little contact between the occupants of neighbouring shelters. In other words, each shelter has become a separate closed community, but differs from the other types of closed communities (for example, a large boarding school) in the fact that the population is dispersed during the daytime, often to widely separated districts, and congregates each night in the common incubator.

It is to the credit of the authorities that the winter has advanced so far without the occurrence of serious or widespread shelter epidemic. It is to be hoped that this satisfactory state of affairs does not lead to a feeling of complacency and cause us to forget the warning uttered by Prof. Greenwood (*British Medical Journal*, 1940, **2**, 677) or to neglect the more simple prophylactic measures. Since our present knowledge is still insufficient to make the universal use of the latest influenza vaccine a practicable measure, we must continue to try the simple methods which are readily available to everyone. If these simple methods succeed in limiting the common infections such as the sore throat and "common cold," then they might well be the first step towards the prevention of a disastrous epidemic similar to that of 1918.—I am, etc.,

J. W. RAE, M.B., Ch.B.,
Feb. 11. Surgeon Lieutenant, R.N.V.R.

Intramuscular Quinine for Malaria

SIR,—I was interested to read the letter from Dr. R. N. Hall (March 8, p. 380) advocating the intramuscular injection of quinine for malaria, for my experience in a mission hospital in Bihar, India, has convinced me that it is an economical and, with ordinary precautions, a safe method of treatment. After drawing up the solution into the syringe we used to wipe the needle carefully with the spirit swab which afterwards was used for purifying the skin. The site we used for injection was the outer aspect of the thigh in the upper part of the middle third. One could distinctly feel the needle pierce the fascia lata, and know that one was really giving the injection intramuscularly.

There is one point I have not seen stressed in the treatment of malaria, and that is the importance of timing the administration of quinine—whether it is given by injection or by mouth. I believe this to be most important, and from experience I found that the most effective time to give quinine by injection was one hour to half an hour before the temperature started to rise. By intramuscular injection the quinine attains its maximum concentration in the blood rapidly, and one's aim should be to get this maximum concentration at the time when the merozoites are scattered into the blood stream. This is shown clinically by the sudden rise of temperature. It is little use to give a 5-grain injection of quinine in the morning if the patient's temperature is not due to rise till the evening, for by that time the concentration in the blood is too weak to be lethal to the merozoites. It is also bad practice to give the injection when the patient's temperature has already risen, as not only does this add to the patient's discomfort, which from the fever is already considerable, but it also has little effect, as by the time the concentration in the blood has risen sufficiently the merozoites are safely sheltered in their new red-cell homes. We found that a single timed injection was usually sufficient to knock out an attack. Even when given by mouth we found the administration of quinine was more effective if given with reference to the temperature chart, but in this case one to one and a half hours was found to be the best time to allow before the expected rise.

The case which finally convinced me of the importance of timing the administration of quinine is, I think, worth reporting. The patient, a doctor, had had a severe attack of blackwater fever. During convalescence she had a slight rise of temperature (99.6° to 100° F.) twice in a day, at about 10 a.m. and 6 p.m., on alternate days. I was at first puzzled by this double rise, but then realized that it might be due to a double infection, one cycle causing the morning and the other the evening rise. On account of the blackwater it was important to give the minimum of quinine, so I gave none by mouth, but had the temperature charted every half-hour and gave a small timed injection of quinine before the morning pyrexia. This prevented the morning rise, but that evening the temperature rose as before. Two days later a second injection given half an hour before the temperature was due to start to rise in the evening knocked that out also, and the rest of the convalescence was apyrexial.

Dr. Hall states that "three daily intramuscular injections of quinine grains 5 are found to cure the acute symptoms." I hope he will try one timed injection and see whether it is not equally effective.

Should the experience of others be the same as my own, a large amount of quinine can be saved, and our patients will be spared some of the very real unpleasant effects which are the result of the "heroic" doses of quinine still sometimes administered.—I am, etc.,

Yeovil, Somerset, March 12. KINGSLEY E. D. DAUNCEY.

Cyclical Mucosal Ulceration

SIR,—The report by Dr. Pappworth of eight cases of cyclical mucosal ulceration in your issue of February 22 (p. 271) contains many points of great interest. I do not wish to go into detail as to a possible difference between ulcus vulvae acutum and those of the author's cases in which a hereditary factor is apparent, but I would point out that if the disorder is clearly associated with menstruation it might be classified among the menstrual molimina. In many cases these are refractory to endocrine treatment, but when looked at as allergic manifestations there seem to be better prospects of a cure. Thus, Gèber (*Brit. J. Derm. Syph.*, 1939, **51**, 265) reports that he achieves remarkable successes in these intractable disorders with injections of serum taken during the menses and applied intradermally daily or every second day. Although Pappworth mentions no allergic symptoms in his cases except angioneurotic oedema once, the very heredity of the symptoms suggests the possibility of allergy as an underlying cause.—I am, etc.,

B. BANETH, M.D.
London, N.W.2, March 8.

Agranulocytosis after Sulphapyridine

SIR,—May I be permitted to suggest that Dr. Dywien's contribution to the toxicology of sulphapyridine (March 22, p. 456) would be far more valuable if he were to record the total dosage of the drug employed. He records his case as one of fatal agranulocytosis following only a short course of treatment with sulphapyridine, but he mentions the fact that the man had had a fortnight's course terminating only a week before and subsequently received further dosages. It is surely now generally agreed that the time factor is of less importance than the total dosage employed, and it would seem as though the inhibitory effect of the drug on the leucopoietic process wears off very slowly.

It would be a pity if such a valuable drug were to fall into disrepute through being represented as more toxic than in fact it is. The case quoted serves to emphasize not the danger of a short course of sulphapyridine but the danger of overdosage and of administering a second course within a short time after the initial treatment.—I am, etc.,

St. Mary Cray, Kent, March 21. BRIAN H. KIRMAN

Vitamin C and Skin Disorders

SIR,—The interesting letter from Dr. L. J. Picton (March 15, p. 420) concerning the value of raw greens prompts me to mention a recent experience concerning the excellent results of turnip juice in the treatment of bottle-fed infants suffering from acute papulo-erythematous eruptions.

The cases under review numbered three and their ages varied from 5 to 12 weeks, while the home conditions were of a low social standard. The mothers of those infants were unable to continue breast feeding once the bed was vacated and the household duties were resumed. Diluted cow's milk and white sugar was adopted as the most convenient substitute. The condition of the skin suggested a preliminary stage in the development of so-called "infantile eczema." The disappearance of rash and general improvement of the baby were noticed within one week of giving turnip juice on the lines suggested by Dr. Picton. The absence of fruit juices, and, indeed, the difficulty of procuring either honey or brown sugar as recommended, leave no option in regard to the use of ordinary white sugar. This is, of course, an objection, though I trust not a serious one.

In older children—from 2 years onwards—raw turnip is invaluable and is always relished by youthful palates which have not yet been perverted by excessive devitalized sugary food. Dr. Picton's interest and good work concerning the relationship between agriculture and health are worthy of the highest admiration and support.—I am, etc.,

Kilmacthomas, Co. Waterford, March 19. P. G. DOOLEY.

Vitamin B_1 in Diphtheria

SIR,—Drs. G. E. Donovan and M. Bannister (March 8, p. 359) present evidence against the value of vitamin B_1 in the complications of diphtheria. I would like to offer criticism of their paper, lest it be too rapidly assumed by those who have only time to read the summaries of papers that substantial proof is offered that the vitamin is valueless in diphtheritic heart failure. None of their "control" cases appear to have had heart failure at all. Of the test cases—that is, receiving the vitamin—three are recorded as having shown signs of failure. One of these (No. 12) received no vitamin for ten days after the appearance of symptoms of heart failure; another (No. 9) was treated from the day symptoms of heart failure appeared, but not for five days after the appearance of palatal palsy; both these recovered. The third (No. 7) is the only one recorded as having had gallop rhythm: it is not stated when symptoms of heart failure first appeared, or how long after treatment with the vitamin was begun death occurred. Treatment was not begun until the twenty-sixth day, but palatal palsy appeared on the fifteenth day.

I submit that these results are wholly inadequate as evidence on the subject, and that the usefulness of the vitamin in diphtheria and other toxic states should still be regarded as *sub judice*. I am interested in the subject as having recently seen two cases in young children not only with gallop rhythm but also with right ventricular failure (oedema, large and tender liver, scanty output of urine), both of whom made rather dramatic recoveries after subcutaneous injection of B_1. Other treatment was, of course, being administered: in one case gallop rhythm disappeared in the course of twenty-four hours and diuresis began almost immediately.—I am, etc.,

Edinburgh, March 21. DUNCAN LEYS, M.D.Oxon.

Vitamin K in Obstructive Jaundice

SIR,—Mr. M. J. Smyth (March 15, p. 417), in reply to my letter (February 22, p. 292) on vitamin K in obstructive jaundice, agrees with most of my statements. While supporting transfusion in cases resistant to vitamin K, he says that the increase in the prothrombin rarely exceeds 10 to 15%. This affirmation loses its value by neglecting to state the volume of blood employed.

He states further that blood is better than plasma and appears to assume that plasma must of necessity be stored. Actually, if fresh plasma is used, twice the amount of prothrombin is introduced for an equivalent volume of blood. Theoretically, the prothrombin of plasma (which has been isolated successfully) should be employed, but as it is unstable it is unlikely to be marketed.—I am, etc.,

Middlesbrough, March 17 R. N. HERSON.

Calcium Requirement

SIR,—I read with much interest Dr. J. P. McGowan's letter on calcium requirement (March 15, p. 421). I am definitely of the opinion that supplementing the dietary calcium with oral administration of calcium salts is not merely useless but can be positively harmful. Dr. McGowan states that certain calcium salts provoke osteoporosis. I entirely agree. It is only reasonable to suppose that the addition of calcium salts to the natural organic calcium of the normal diet precipitates the latter into relatively insoluble compounds which are eliminated by the bowel as sulphates, carbonates, etc.

The Craven district of Yorkshire is tolerably prosperous. It is essentially rural. Dairy produce, as well as mutton, pork, etc., are plentiful in normal times. It is a limestone country and the vegetation is rich in lime salts. The stocks benefit accordingly. Yet rickets is prevalent and dental caries rampant. I believe the secret is not the diet but the unusual hardness of the water. The incidence of lithiasis, renal as well as biliary, is remarkable. I have noticed similar tendencies in other districts where the water is unduly hard.

In the Island of Lewis rickets is unknown and the incidence of dental caries remarkably low. The diet is certainly wholesome with an adequate calcium ratio, but the water is very soft—so soft that a minimum of soap is required for washing purposes. But the normal diet of the Cravendale people can be scarcely less wholesome or less rich in calcium.

Water which is unduly hard by reason of lime in suspension or solution can actually be softened by the addition of more lime to form and precipitate lime salts. Unless I am mistaken, the wise people of Aberdeen had recourse to this dodge to soften the Dee water used in the Granite City. By the same analogy it is not unreasonable to think that natural calcium plus phosphate present in food and available and assimilable as such can be rendered insoluble and unavailable by the drinking of hard water.—I am, etc.,

Biggar, Lanarkshire, March 18. J. MACLEOD, M.D.

Malignant Measles?

SIR,—I have been much interested in the comments aroused by the note I made on the case diagnosed by me as "malignant" measles (March 8, p. 380).

Unfortunately the child was seen only once after the development of the rash and that at 2.0 a.m. in the poor light of a cottage. The child was already moribund and was disturbed as little as possible for purposes of examination. The parents did not wish a post-mortem examination to be made, and as I was not in doubt concerning the diagnosis of measles I did not insist, although for the purposes of discussion and finality it would obviously have been desirable.

Comment has been mainly focused on whether this case ought not to have been diagnosed as the Waterhouse-Friedrichsen syndrome or suprarenal haemorrhage. Clinically

the child presented the features characteristic of this condition —sudden onset, rapid fatal course with cyanosis, circulatory failure, and subcutaneous haemorrhages—and the point at issue is whether this syndrome was due to measles or to some other cause. Kunstadter (*Arch. Pediat.*, 1939, **56**, 489) estimates that 65 to 70% of cases in which bacteriological investigations have been made have been shown to be due to the meningococcus, but he points out that other infections have been mentioned as causative agents—among them measles.

In this district only one case of cerebrospinal meningitis has occurred during the last twelve months, and that was several months prior to the case under discussion. This latter was seen, however, during the height of an exceptionally widespread measles epidemic.

Whilst a morbilliform eruption can occur in suprarenal haemorrhage *not* due to measles (Grace, Harrison, and Davie, *Lancet*, July 27, 1940, p. 102) there is no reason to assume that measles is absent in the presence of a typical eruption even when this *is* accompanied by signs of suprarenal haemorrhage, unless some other organism is found to be responsible. Some of the recorded cases in which cultures have been made from blood and cerebrospinal fluid have yielded negative cultures (Sachs, *Ann. intern. Med.*, 1937, **10**, 1105).

With regard to Dr. G. P. Goodwin's comment (March 22, p. 462) that no mention was made of Koplik's spots or of the usual prodromata of measles, it is to be noted that the former disappear as the rash develops and are therefore not of value in a case like this unless they happen to have been looked for before any other suspicion of measles arose.

I agree with Dr. Price Williams (p. 462) that "blackness" does not necessarily imply malignancy, although in this case both terms were justified. In the present epidemic a typical case of morbilli bullosi was seen by a colleague. The course of the illness was prolonged for several days but ultimately reached a fatal conclusion. Another typical case of measles suddenly developed convulsions and went into a state of coma from which it did not recover. This may seem to be a high proportion of fatal cases for one district, but over three hundred cases have been notified this year, and this number could doubtless be increased by cases not seen by any doctor.—I am, etc.,

Tiverton, Devon, March 23. AUDREY Z. BAKER.

Hospitals Radon Centre

SIR,—As the result of a generous gift from the British War Relief Society of New York, further supplies of radon are now assured. The gift was made to the British Hospitals Association, who have asked the Middlesex Hospital to administer it. This new supply is intended for the use of hospitals throughout the country, and no distinction will be made between requisitions for paying and non-paying patients. It is hoped to increase the amount of radium in solution at this new centre when the demand warrants it.

In the first instance it will be necessary to charge all hospitals for supplies of radon, and it has been decided to charge for it at the lowest basic rates obtaining at the Medical Research Council Radon Centre—namely, one shilling a millicurie, with a reduction to sixpence a millicurie for any quantity in excess of fifty millicuries; the minimum charge for any radon requisition will be one guinea. It is hoped that in the near future some arrangement will be possible whereby the burden of such payments may be lightened. Applications for radon may now be sent to the Hospitals Radon Centre, c/o Barton Lime Co., Barton-in-the-Clay, Bedfordshire; telephone Hexton 210.—I am, etc.,

Middlesex Hospital, W.1, March 24. SIDNEY RUSS.

E. Wolff (*Arch. Pediat.*, 1941, **58**, 1), who records eight illustrative cases under the name of "buccal spots," describes a new sign in influenza and the common cold consisting in the appearance in 70% of the patients within the first three days of small white specks in the mid-area of the mucous membrane of the cheek, opposite the bite-line of the teeth. The author says that they are most frequently situated (1) between the anterior and middle thirds, (2) in the centre, and (3) between the middle and posterior thirds of the line. They are distinct from traumatic lesions, Koplik's spots, and aphthous stomatitis.

Obituary

Dr. ARTHUR DOUGLAS WEBSTER, O.B.E., died at his home in Mansionhouse Road, Edinburgh, on March 16, aged 85. A native of Nova Scotia, he graduated M.D., C.M. of McGill University in 1878, and, coming to Edinburgh soon afterwards, obtained the licence of the two Scottish colleges. He was admitted F.R.C.P.Ed. in 1884, took the B.Sc. of Edinburgh University in Public Health in 1888, and proceeded to the D.Sc. in 1900. Dr. Webster was a keen Volunteer in the years before the last war, serving in the ranks before he was gazetted to a commission as medical officer of the 4th Battalion Royal Scots (Queen's Edinburgh). On the outbreak of war in August, 1914, he offered his services and was appointed medical officer of the 1st Edinburgh Battalion (Kitchener's Army) 15th Royal Scots and attained the rank of Lieut.-Colonel R.A.M.C.(T.); for his military services he was awarded the Volunteer Decoration and the O.B.E. Dr. Webster, who had been a member of the British Medical Association for sixty-one years, was a Fellow of the Royal Physical Society of Edinburgh and the Obstetrical Society of Edinburgh, and an external member of the Royal Medical Society. He had long held the post of examiner of blind persons for the South-East District of Scotland. His eldest son is Dr. J. H. Douglas Webster, honorary director of the Meyerstein Institute of Radiotherapy, Middlesex Hospital.

Dr. WILFRED SCOVIL SODEN, who died suddenly on March 13 at Winchcombe, Gloucestershire, aged 52, received his medical education at Cambridge (St. John's College) and St. Bartholomew's Hospital. He graduated B.A. with honours in the Natural Sciences Tripos of 1910 and took the English Conjoint qualifications in 1913 and the M.B., B.Ch. degrees in 1920. From 1913 to 1915 he worked at the Metropolitan Hospital, first as house-physician and later as house-surgeon, and then as pathologist and registrar. He served in the last war with the rank of Captain, R.A.M.C.T., and was mentioned in dispatches, and after the armistice remained in Egypt and served for a time as examiner at the Cairo School of Medicine. It was during this period that he wrote his M.B. thesis on the work of a stationary hospital in Palestine. At Winchcombe, where he began practice in 1921, Dr. Soden was appointed medical officer and public vaccinator for the Vale District, and he became honorary surgeon to the Winchcombe Hospital, which he was largely instrumental in establishing in 1927. He had been a member of the British Medical Association for the past eighteen years. By his death Winchcombe and the surrounding countryside has suffered a great loss.

We regret to record the death by enemy action of Dr. HILDA BEATRICE GRINYER. She studied at the London School of Medicine for Women, taking the diplomas of M.R.C.S. and L.R.C.P. in December, 1938, and in February, 1940, was appointed house-surgeon at the Manchester Royal Eye Hospital, where she worked most assiduously until her untimely death during an air raid on Manchester. It was her custom during the "alert" periods to help in the carrying of children down to the shelter and to assist the patients in every way.

The sudden death occurred on March 21 of WILLIAM ADAMS CLARK at the age of 77. He graduated M.B.Lond. after his curriculum at St. Bartholomew's Hospital, and proceeded to the M.D. three years later. After holding several minor appointments he settled in 1895 in practice in Penge, where he died. Here he had a large area from which he drew patients, and he was greatly respected owing to his thoroughness in diagnosis and skill in treatment, and for his kindness to rich and poor alike. He was school medical officer for the Penge educational authority. Dr. Adams Clark was a staunch evangelical churchman, and much interested in the activities of the congregation of which he was a member. For many years he had been a member of the B.M.A. All three of his children—a son and two daughters—are following their father's profession. Some years ago he had a motor accident from which he did not appear ever to have fully recovered, but he died suddenly from myocardial degeneration.

Universities and Colleges

UNIVERSITY OF OXFORD

Election to Board of Faculty of Medicine

1 election of two members of the Board of the Faculty of edicine will be held on June 4. The members elected will me into office on the first day of Michaelmas Term, 1941. d will hold office, the senior for two years and the junior r one year from that day.

The General Medical Electorate consists of all Oxford aduates in medicine who are members of Convocation. ie Board of the Faculty of Medicine includes two members :cted by the general medical electorate who must be members that body and of whom one at least must be a person gaged in teaching one or more of the clinical subjects of the iculty.

Nominations of duly qualified candidates for election will received by the Secretary of Faculties at the University egistry up to 10 a.m. on May 14. Each nomination must signed by six members of the general medical electorate. id no candidate will be eligible whose nomination has not :en received by that date.

UNIVERSITY OF LONDON

ne degree of Ph.D. for internal students has been awarded Mary T. Franklin of the London School of Hygiene and ropical Medicine.

UNIVERSITY OF BRISTOL

M. Yoffey, M.D., F.R.C.S., has been appointed to the hair of Anatomy in the University in succession to Prof. E. Whitnall, who retires at the end of the current session.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

he following candidates have satisfied the examiners for the iploma of the College:

Marie H. Calverley, L. E. Cowan, Ursula M. Dick, Marjorie O. unster, D. S. Foster, R. R. Gordon, C. N. Gosse, Ruth M. owitt, Iola Ll. T. Jones, Agnes MacF. D. Milne, J. Overton. lary A. Rogerson, C. R. Sluming, Christine M. Stacey, Evelyn E. eed, Lucy M. Sutcliffe.

The Services

HONORARY SURGEON TO THE KING

ir Commodore Frank Cuninghame Cowtan, R.A.F., has been ppointed Honorary Surgeon to the King in succession to ir Marshal Sir Victor Richardson, K.B.E., C.B., R.A.F.

D.D.M.S. APPOINTMENT

olonel (Temporary Brigadier) O. W. McSheehy, D.S.O., .B.E., late R.A.M.C., has been appointed a Deputy Director f Medical Services and has been granted the acting rank f Major-General.

R.A.F. AWARDS AND MENTIONS IN DISPATCHES

The George Medal has been awarded to Flying Officer Kenneth Leopold George Nobbs.

One night in November, 1940, an aircraft caught fire in he air and crashed in the vicinity of an aerodrome. Flying Officer Nobbs hastened to the scene of the accident and, although the aircraft was burning fiercely and machine-gun bullets were flying in all directions, he at once entered the wreckage. He succeeded in pulling out the trapped air gunner, and after carrying him to a safe distance extinguished his burning clothing just before the petrol tanks exploded. Although the air gunner subsequently died of his injuries, Flying Officer Nobbs displayed the utmost courage and an entire disregard of danger in his efforts to save the air gunner's life.

Flight Lieut. David Anderson Smith, A.A.F., has been appointed an M.B.E. (*Military Division*) in recognition of distinguished services rendered in operational commands of the Royal Air Force.

Flight Lieuts. William Noel Whiteside and James Leonard Brown, R.A.F., and Flight Lieut. Edward Conrad Gross, A.A.F., have been mentioned in dispatches.

CASUALTIES IN THE MEDICAL SERVICES

ROYAL ARMY MEDICAL CORPS

Captain THOMAS ELLIS MITCHELL died at Birmingham this month, aged 34. He was the only son of the late Dr. and Mrs. T. E. Mitchell of Old Hill, Staffs, and was educated at the University of Cambridge and Guy's Hospital, qualifying L.M.S.S.A. in 1933. Before the war he was in partnership with Dr. Hugh Stevenson at Old Hill.

Medical Notes in Parliament

Nursing Demands and Mobilization of Women

The mobilization and registration of women for war service were discussed in the House of Commons on March 20. Opening the debate for the Ministry of Labour, Mr. R. ASSHETON said that Mr. Bevin had appointed to help him in his work a committee of women, including Dr. Summerskill. Before this year was out there would be a demand for women to take the places of men in every occupation where it was possible for them to do so. There were also demands in the public health and nursing services. On April 19 all women born in 1920 would be registered and would soon be followed by the next older age group. All women, married or single, would have to register unless already in the women's services or in the nursing services attached to the armed Forces. The greatest care would be taken to avoid calling on women with young children. No woman who was pregnant would be called up compulsorily. It would be wise to obtain the services of unoccupied women in the older age groups before taking away women of 20 or 21 who were doing useful work. Registration would be followed by interviews, at which an important consideration would be the woman's health. It was not proposed that women should be examined by a medical board, but it would be possible for women to produce medical evidence of any infirmity or disability. The Ministry of Labour would be entitled to obtain an independent medical opinion.

Miss WARD asked Mr. Assheton to see whether justice was being done to nurses. A Division of Nursing in the Ministry of Health had been asked for, with people in charge who were qualified and experienced in the nursing world. Local authorities had been able to make arrangements about superannuation for nurses, but no voluntary hospital had been able to accept the responsibility of keeping up the payments. The War Office had not come to a decision with the Treasury to treat properly the nurses in the armed Forces of the Crown in regard to superannuation.

Viscountess DAVIDSON said that in a civilian hospital which would soon have some 1,500 beds, a large percentage of the domestic servants on the staff aged 20 or 21 left, within twenty-four hours of Mr. Bevin's speech on the conscription of women, to enlist in one of the three Forces, being convinced that compulsion would follow. She asked for an instruction that such women should not leave their present jobs until they were needed.

Miss HORSBRGH said the work done in the hospitals took second place to none in the country, whether it was domestic work or the work of nurses, doctors, or ambulance personnel. She thought the call to that service would be answered. The Civil Nursing Reserve had trained many thousands of women, but there had been difficulty with women who did not wish to leave their homes. Greater mobility was necessary because the fever hospitals and some of the special hospitals were not getting sufficient recruits. However, there had been a steady increase in the numbers coming in, but new recruits were wanted who would go anywhere and nurse everyone and would stay in one place until it was found that their services were more urgently needed elsewhere. Arrangements had now been made for a Nursing Division of the Ministry of Health. Difficulties associated with the superannuation could be overcome, but it was very difficult to do so in wartime. Women over 30 as nursing auxiliaries could obtain a short instruction in hospitals, and arrangements were being made for nursing training from now on of a more comprehensive character.

The Ministry hoped to form a Central Register for those who came into the nursing profession merely for the war or who hoped to work in that profession later. The Ministry would fix a minimum rate of salary during the war, and hospitals to which the probationers were sent from the Central Register would be required to pay this. She did not believe, now there were calls to women to work in munition factories, that the call for nurses would not be answered.

Dr. EDITH SUMMERSKILL said it was taken for granted that there would be no calling up of expectant mothers, but there would be expectant mothers in the factories. An employer committed an offence if he knowingly engaged a woman during the four weeks after childbirth, but could employ her right up to childbirth. The Midwives Institute and other organizations pressed for the Minister to issue an order making it an offence for a woman to be employed during the four weeks before confinement. The Minister should introduce a Regulation right away dealing with this matter. She asked the Minister also to consider allowing a nursing mother to have time to feed her baby at work.

Milk Supplies

In the House of Lords on March 18 Lord WOOLTON said the Government had decided that in these abnormal times it could not adopt the recommendations made by Lord Perry's Committee on the distribution of milk. By maintaining an unrestricted supply of milk to nursing and expectant mothers, to young children, and to children under the milk-in-schools scheme the Government would give priority to some 5,500,000 people. He was also arranging to secure the maintenance of milk supplies to hospitals and, under prescribed conditions, to certain types of people who were ill. The Ministry of Food, with the Health and Education Departments, had removed many of the difficulties which arose in the milk-in-schools scheme as a result of war and evacuation. He had decided to restrict the consumption of milk by the ordinary man and woman, and had asked dairymen to reduce from the middle of April their domestic sales by approximately one-seventh. He would require bakers and flour confectioners to dispense with milk and would continue the ban on the use of fresh cream, and that on the use of milk in making synthetic cream and ice-cream.

State Medical Service

Mr. GROVES asked whether the Minister of Health, in view of the fact that medical services directly or indirectly controlled by the Government embraced the armed Forces, the emergency medical and air-raid precautions services, medical benefit under the National Health Insurance Acts, public assistance, services in respect of factory workers, and medical officers of health, would consider instituting a State Medical Service to solve the problem of the distribution of medical man-power between the claims of the civilian population and the armed Forces. Mr. BROWN replied on March 25 that the present time was not opportune for considering this suggestion. Machinery for securing that the best use was made of the medical man-power available had been in existence since the beginning of the war.

Nursing Homes in Central London.—On March 19 Mr. LIDDALL asked whether the Minister of Health would, as part of reconstruction planning, arrange with the London County Council gradually to abolish the derelict houses in slum areas around the Baker Street district of Marylebone, which had been converted for use as private nursing homes, and to replan the whole private nursing home system and location in Central London. Miss HORSBRUGH answered that the needs of adequate medical services would be borne in mind in the plans for reconstruction of large areas, but it was too early to make any statement on the position of particular areas or particular services after the war.

Batteries for Hearing Aids.—Captain WATERHOUSE stated on March 20 that difficulty in securing batteries for use with electrical hearing apparatus was due to increasingly heavy Service demands for miniature cells. The problem of arranging for the use of other types of cell in hearing aids was being examined in consultation with the manufacturers. Meanwhile, supplies of miniature cells were being released.

Notes in Brief

The arrangements for the medical care of the Home Guard are under review. Mr. Groves, in asking about this, said that in many cases the Home Guard was setting up its own medical service.

No. 9

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended March 1, 1941.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included); (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1941					1940 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

he commoner acute infectious diseases. scarlet fever and sles have slightly increased in incidence during the week. se two diseases, and also whooping-cough, have been tend- to increase in the last few weeks but with considerable uations from week to week. Although they are more alent than at the corresponding period of last year, the irregular rate of weekly increase suggests that large- epidemics are unlikely.

Cerebrospinal Fever

or the first time this year the number of notifications has pped, and experience shows that it is likely to decline her in the coming weeks, although not necessarily in ilar fashion. Despite the decrease in the notifications, number of administrative areas involved has risen during week from fifty to fifty-one; the following are most vily affected: Lancaster 54; Yorks. West Riding, 31; morgan 27; Warwick 23; London 22; Chester 18; ex 14; Middlesex 14; Stafford 14; Northumberland Devon 11; Surrey 10; Durham, Gloucester, Hertford, Kent 9 each; Somerset 8; Norfolk 7; Berks and South- ton 6 each. The details of the notifications in counties rding more than 12 in the week indicate that the disease videly scattered in each administrative area, probably affect- the rural and urban districts per head of population as ch as the county boroughs. For the week ending March 15 ifications amounted to 330.

n Scotland notifications rose from 70 to 97 and administra- areas involved rose from 23 to 26; the disease is preva- t in the counties of Ayr 7, Fife 5, Lanark 4, Moray and irn 4. Clackmannan 3, and the boroughs of Glasgow 32, nburgh 13, Kirkcaldy 4. Falkirk 3.

Dysentery

Although dysentery has fallen since last week it is more valent than usual, chiefly due to localized outbreaks of nsiderable magnitude in institutions. Over five-sixths of the al occurred in five administrative areas, the remaining een areas involved recording single or small numbers of ses only. The areas chiefly affected are Essex 52 (Colches- M.B. 48. Brentwood U.D. 4); Yorks. West Riding 31 ieffield 1, Wakefield 4, Aireborough U.D. 5, Goole M.B. 18, dsey M.B. and Shipley U.D. 1 each); Bedford 29, all in gleswade R.D.; Lancaster 23 (Manchester 14, Lancaster B. and Warrington 1 each, Blackburn R.D. 2, Whiston D. 5); London 17 (Wandsworth 10, and 1 each in Chelsea, lborn, Islington, Lewisham, Paddington, St. Marylebone, d Stepney). Details are available of the Goole outbreak, which 1 death has been recorded so far. Of 17 cases long the infirm inmates in one block of the county insti- ion one of the patients came from Wakefield, where two ses had previously been reported, but the source of the tbreak has been ascribed to two carriers of the disease, acuees from Hull and London respectively. For the week ding March 15, 146 cases of dysentery were notified.

In Scotland cases were recorded in the counties of Aberdeen Fife 3. Lanark 1, Renfrew 1, and the boroughs of Aber- en 2, Dundee 7, Edinburgh 5, Glasgow 1. At the time of ing to press there are reports of a widespread outbreak of ratyphoid B fever in the counties of Moray and Nairn, verness, and Ross, but no details are available as to source numbers affected.

Influenza for Week Ending March 15

In the week ending March 15, 132 deaths were ascribed influenza in the great towns, 67 fewer than in the previous eek. Of these deaths, 6.8% were at ages under 25 and 1.54% at ages over 65. In the County of London 15 deaths ere registered (13 in the previous week). The proportion of tal deaths coming from the South-Eastern Area was 28.36%. would appear that the winter epidemic is now over.

Medical News

The names of Dr. Mary Barrow of Birmingham and Dr. Andrew Campbell Clarke, Divisional Police Surgeon, Salford Police Force, have been brought to notice for brave conduct in civil defence.

Lord Horder will read a paper on "The Modern Troglodyte" before the Royal Society of Arts (John Adam Street, Adelphi, W.C.) on Wednesday, April 2, at 2.30 p.m., when Mr. Ernest Brown, Minister of Health, will preside.

At the next meeting of the Medical Society of London, to be held at 11, Chandos Street, Cavendish Square, W., on Monday, March 31, at 4.30 p.m., a discussion on "The Factors influencing the Healing of Wounds" will be introduced by Dr. John M. Converse from the U.S.A. and Mr. Alan H. Hunt.

The next meeting of the Shaftesbury Military Hospital Medical Society will be held at the hospital on Tuesday, April 1, at 3 p.m., when Lord Horder will deliver an address on "The Future of Medicine." An extraordinary meeting will take place on Saturday, March 29, at 3 p.m., at which a discussion on "The Dyspeptic in the Army" will be opened by Dr. Charles Newman and Mr. Reginald T. Payne.

At the next meeting of the Society of Public Analysts and Other Analytical Chemists, to be held at 4 p.m. on Wednesday, April 2, at the Chemical Society's Rooms, Burlington House, W.1, three papers will be presented and discussed, including two on the determination of arsenic in foodstuffs contaminated with arsenical war gases. Guests introduced by members are welcomed at the meetings by the council, but they are reminded that the proceedings are strictly private.

The United States National Foundation for Infantile Paralysis will hold a semi-annual meeting of its medical committees on May 15, when applications for grants for the study of the cause, prevention, and treatment of the disease will be considered.

According to *Nature* of March 8 the Swammerdam Medal for 1940 has been awarded to Prof. G. W. Grijne of Amsterdam, the Nestor of Dutch physiologists. The six previous recipients have been K. T. E. von Siebold (1880), Ernst Haeckel (1890), K. Gegenbaur and Hugo de Vries (1910), Max Weber (1920), and H. Spemani (1930).

The issue of *Science* for February 7 is devoted to reports of the recent Philadelphia meeting of the American Association for the Advancement of Science and associated societies. The programme of the medical section was entirely given up to human malaria.

At the half-yearly meeting of the executive committee of the Duke of Gloucester's Red Cross and St. John Fund it was announced that over £5,000,000 have been raised by voluntary contributions since the outbreak of war.

The American Academy of Arts and Sciences has awarded nearly 16,000 dollars to be divided equally among four scientists for their contributions to the treatment and care of genito-urinary diseases. The money comes from the Amory Foundation established in 1912. Three of the prizes go to Americans: Dr. Joseph F. McCarthy of New York, Dr. Carl Richard Moore of Chicago, and Dr. Hugh H. Young of Johns Hopkins. The fourth will go to a European scientist whose name will not be revealed at present.

Dr. John F. Fulton, Sterling professor of physiology at Yale University, has presented to the Yale Medical Library a collection of books and Government documents bearing on military medicine published in England since the beginning of the war.

Dr. Evarts A. Graham, Bisby professor of surgery, Washington University School of Medicine, St. Louis, Mo., has had conferred on him the honorary degree of doctor of science by the University of Pennsylvania.

Australia, which has the lowest infantile mortality in the world, has fitted out a children's sanitary train to provide help for mothers and children in out-of-the-way country districts.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE NO.—B.M.A. and *B.M.J.*: EUSTON 2111.

TELEGRAPHIC ADDRESSES.—EDITOR, *Aitiology Westcent, London*; SECRETARY, *Mediscera Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

QUERIES AND ANSWERS

Sjorgen's Syndrome

DR. MARGARET COLLS (Isle of Man) writes: I should be grateful for information on the above syndrome. Where can I find an account of it in the medical literature? I have a female patient aged 47 who for the past six years has suffered from complete absence of saliva, from dysphagia, extreme dryness of the skin, and alopecia necessitating the wearing of a wig. Her mouth is in a very unhealthy condition from gingivitis and bleeding of the gums. She has great difficulty in masticating her food. Mouth washes, ascorbic acid tablets, and an acid mixture before meals have been prescribed, but without much alleviation of her distressing condition. Can someone suggest further treatment?

Rose-hip Jelly and Wild Herbs

MISS GWENDOLINE BOWES (Grange-in-Borrowdale, Keswick) writes: I think that Dr. W. J. Burns Selkirk (March 15, p. 426) would find the following recipe for rose-hip jelly pleasing: Take the outside only of the rose-hips and press into an enamel pan, and just cover with water. Simmer until very soft and rub through a sieve. To each pound of pulp add 3/4 lb. of sugar and 2 oz. of preserved ginger. Boil until the jelly sets when tested. The above is taken from *The English Cookery Book*, by Lucie G. Nicholl, published by Faber and Faber. There is an excellent section "The Rambler's Harvest" giving many interesting country recipes. The old suggestion of cooking the fronds of young bracken—almost asparagus—may be raised again this year. Five of us made the experiment last, gathering with loving care, and cooking the greens until tender, serving with butter sauce. Never again: we were reminded of a very bitter dose of quinine. May I add that mustard and cress grown on blotting paper, kept moist, is very delicious, and, given seasonable sun, yields a quick result.

DR. E. SAKOSCHANSKY (Southampton) writes: Dr. Burns Selkirk inquires what book dealing with the use of wild herbs would be recommended. *Wild Foods of Britain*, by Jason Hill (Adam and Charles Black, London) is a veritable mine of information. Hill gives a recipe for making hawthorn jelly from hawthorn fruit (haws); he states that a jam is made in Scotland from wild rose hips, but gives no recipe, though he states that the hips of the wild rose are a commercial source of the anti-scorbutic vitamins, and he gives an interesting account of the use of the dandelion.

Herbs for Flavouring Food

DR. ROBERT BUXTON (Weston-super-Mare) writes: Two letters appeared in your issue of March 15 referring to the use of herbs for flavouring food which I read with interest, as I have a herb-garden. Vegetables will this year be more important than ever as part of the national diet. However, as a nation we are unenterprising in the way we cook them, in the few varieties we use, and in the neglect of herbs in all kinds of dishes. Herbs are easy to grow and provide a variety of flavours on the table and colours in the garden. Many herbs can be used in the kitchen, but only a few are necessary, the others being for the connoisseur. To anyone interested I would recommend buying in April the following herbs: balm, chives, tarragon, chervil, winter savory, borage. These are obtainable from Miss Eleanor Sinclair Rohde, Cranham Lodge, Reigate, Surrey, together with books on the subject written by her. Herbals are full of folk-lore and charm—for example: "If poisoned by your step-mother, drink horehound hot from the fire."

Income Tax

Medical Boards—Fees—Schedule E

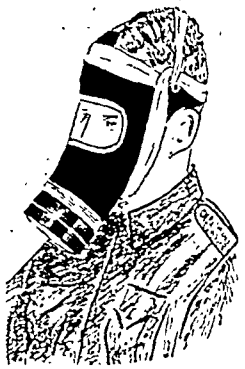
"A. M." holds an appointment on a Medical Board, and being on the B.M.A. Ophthalmic List deals with cases referred by other Medical Boards. Are the fees from the latter work assessable under Schedule E?

*** Schedule E applies to "all salaries, fees, wages, perquisites or profits whatsoever . . ." paid to a person exercising an office or employment of profit. The language used seems wide enough to cover the fees received for the referred cases.

Fall in Earned Income

"A. B.'s" earnings for the year to December 31, 1940, show a fall of 18%—i.e., less than the statutory requirement of 20%—but a comparison between the amount of the assessment and the earnings for the year to March 31, 1941, will probably show a fall in excess of 20%.

*** "A. B." can claim to base the comparison on the year to March 31, 1941. The most convenient method is probably to take three-quarters of the 1940 profit plus the amount of the profits for the three months to March 31, 1941, as representing the earnings of the year to that date.



LETTERS, NOTES, ETC.

In Gratitude to Medical Colleagues

DR. LEWIS G. GLOVER, Honorary Treasurer of the Royal Medical Benevolent Fund, writes: I desire to acknowledge gratefully through your columns a donation of £50 which I have received from a doctor as a mark of appreciation of the great kindness and consideration he has received from his medical colleagues during his wife's recent illness, which necessitated an extensive abdominal operation. He adds: "It is a very small return for all the kindness and skill that has been expended on my wife. I wish my means allowed for a bigger cheque, but I hope that I may be helping, through the Royal Medical Benevolent Fund, some unfortunate fellow medico or his dependants."

How to Make a Civilian Respirator More Serviceable

DR. THOMAS MARLIN (London, W.1) writes: People who have to move about vigorously while wearing the civilian gas mask experience a certain amount of inconvenience, because the mask, owing to its non-rigid construction, flaps about from side to side, and is apt to pull away from the face. This can be prevented by the following simple method devised by Mr. A. L. Bunker, an ambulance instructor in a Home Guard battalion. Take a strip of cloth 54 inches long and 2 or 3 inches wide and place it over the crown of the head so that one end is shorter than the other. The short end should reach to the breast pocket. Now, holding an end in each hand, bring the longer end under the point of the jaw and up the other side of the face. Cross it with the other end above the temple (see illustration). Carry the longer end round the back of the head and the shorter end across the forehead. Tie the two ends together where they meet.

Plaster Casts for Fractures

Messrs. T. J. Smith and Nephew, Ltd., of Neptune Street, Hull, have prepared for issue to the medical profession only a pamphlet entitled "The Preparation of Plaster Casts, with Special Reference to the Use of Wide 'Cellona' Material." This is available on application to the medical department of the firm at the address given above.

Calcium Lactate: Correction

DR. J. A. BROWN (Birmingham) writes: I apologize for the error in the prescription published under the above heading (March 22, p. 468). The quantities are obviously transposed and the prescription should read:

℞ Calcii carb. 3j
Ac. lactic. 3iij
Aq. .. .. ad 3viij

F.M. Sig.: 3ss t.d.s.

REHABILITATION OF THE INJURED

BY

E. A. NICOLL, M.D., B.Ch., F.R.C.S.Ed.

Surgeon-in-Charge, Fracture Clinic, Mansfield General Hospital; Surgeon-in-Charge, Miners' Rehabilitation Centre (Midland Counties), Berry Hill Hall

Since the outbreak of war considerable interest has been aroused in the subject of "rehabilitation," and it is therefore important that the meaning and application of this word should be clearly defined. Unfortunately, different people use it in different senses. Sometimes it is used to denote the training of cripples for special occupations adapted to their disabilities; but this is not rehabilitation. It is vocational training, and should always be referred to as such. Rehabilitation is an entirely different process, the object of which is to cure or reduce disability resulting from trauma so that the injured person is enabled to return to his ordinary work in the industry in which he was formerly employed or, failing that, to useful alternative work in the same industry. Vocational training is essentially a process of compromise with disabilities that must be accepted as permanent, and is necessary only in the relatively few cases in which rehabilitation fails. The more thoroughly the problem of rehabilitation is tackled the less need there will be for vocational training.

Standardization of Results

It is obvious that the difficulty of the problem depends on the nature of the work for which the patient has to be reconditioned. If a carpenter sustains a compression fracture of the spine or a fractured femur he will be fit for full work at a stage in which a miner is only fit for what is euphemistically described as "light work" in a pit. It is difficult to suggest a universal standard by which results may be assessed and compared, but in my own work amongst injured miners return to full work has been adopted as the criterion of full recovery. Return to permanent "light work" is classified as permanent partial disability, and inability to do any useful work in a pit is regarded as permanent total disablement. To appreciate these standards something must be known regarding the nature of a miner's work. To get to it he usually has to walk several miles underground on difficult surfaces. The head-room of his working space averages about three and a half feet, but may be as low as two feet. The average amount of coal which each man hews and loads at the coal face under these cramped conditions is twelve tons per shift, but it may be as high as eighteen in an easily worked seam. Finally, there is no really light work in coal-mining, and the jobs that are usually given under this heading are the equivalent of full work in most other industries.

These standards are unusually severe tests of recovery, but they have the advantage of searching out imperfections which less exacting methods fail to disclose. Half the cases in my fracture clinic—that is, about 1,200 a year—are those of miners injured at work, and it is in respect of these that statistics are kept regarding restoration of working capacity.

The Miners' Rehabilitation Centre

My experience in rehabilitation as a special problem is derived from the Miners' Rehabilitation Centre at Berry Hill Hall. This centre was established by the Midland Colliery Owners' Mutual Indemnity Company in association with the Bolsover and Butterley Colliery Companies, and is at the service of the entire coalfield, which extends over seven counties. It is administered by a committee consisting of two representatives of the Owners' and two representatives of the Miners' Union. The rehabilitation problem in coal-mining is a very big one because the accident rate is so high (five times higher than the average industrial accident rate), the injuries are of a severe type, and there is no really light work to offer disabled men. Among the 100,000 men employed by the owners concerned in this scheme there are 18,000 accidents a year in respect of which compensation is paid; 6,000 of these men are totally incapacitated for more than a month, and 800 for more than six months. It is chiefly from the latter class that the cases for the rehabilitation centre are drawn. In my own fracture clinic about 15% of the cases are transferred. These are of three kinds:

(*a*) Severe injuries—e.g., fractured femur, compression fracture of the spine—which, on past records have a high risk of permanent partial disablement as judged by the criterion of return to full work as miners. These cases are transferred as soon as the men are capable of undertaking daily exercises.

(*b*) Cases which have come to a standstill short of full recovery, however simple the original injury might have seemed. Formerly these men were sent back to light work in the hope that it would prove remedial and that they would progress to full work in the course of time. A recent survey has shown that in fact 60% of such men remain permanently on light work. The reason for this is not far to seek. Light work, if it is to have any remedial value, must be selected, supervised, and graduated by the surgeon just the same as any other form of occupational therapy. In actual practice light work usually terminates the surgeon's connexion with the case.

(*c*) Cases in which some permanent disablement is inevitable from the outset but in which much can be done to reduce this and so restore to permanent light work patients who might otherwise have been totally disabled.

The Miners' Rehabilitation Centre is a modernized country mansion with 100 acres of grounds, to which a first-class gymnasium and a remedial workshop have been added. It is not part of a hospital, and this in my opinion has definite psychological advantages. Patients who live near enough are allowed to attend daily, but

those from further afield and all who are under-nourished or whose home circumstances are in any way unsuitable are kept in residence. The treatment is intensive and individual, and consists of graduated remedial exercises, occupational therapy, physiotherapy, and remedial games. Perhaps most important of all is the daily and hourly preaching of the gospel of rehabilitation—that recovery can only come by the unremitting hard work of the patient himself.

Importance of Soft Tissues

Before describing these methods of rehabilitation in detail I would like to draw attention to certain general principles which have an important bearing on the earlier stages of treatment. Recovery of function depends ultimately on the muscles, which may be affected either directly at the time of injury or by atrophy due to disuse. Direst trauma may mean actual laceration as in a compound fracture, simple contusion as in the case of a long bone ensheathed in muscles (e.g., fractured femur), or over-stretching as in hyperflexion fractures of the spine. The difference between immobilizing a normal muscle and immobilizing a damaged muscle is that whereas both undergo atrophy, the latter is much more liable to undergo contracture as well, owing to the organization of traumatic exudates into fibrous tissue. The degree of contracture will depend on the severity of the initial damage and the duration of immobilization, and its effect will be to cause limitation of movement in the joint over which it acts. If, for example, an uninjured quadriceps is immobilized for ten weeks in the treatment of a fractured tibia and fibula full movements of the knee-joint are usually recovered within a week of removing the plaster; but if a contused quadriceps is immobilized for ten weeks in the treatment of a fractured femur, flexion of the knee-joint takes months to recover, and the majority of cases never recover full flexion.

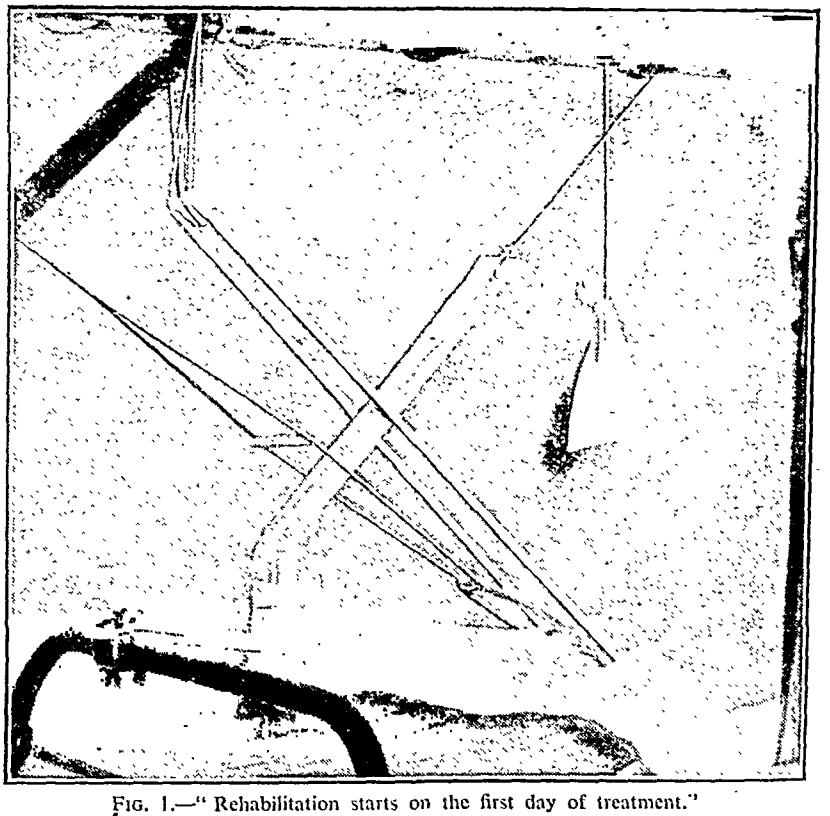

FIG. 1.—"Rehabilitation starts on the first day of treatment."

The chief problems encountered in the later stages of rehabilitation result from the immobilization and disuse of damaged or normal muscles—loss of power due to atrophy, stiffness due to contracture, and pain due to localized fibrosis. These are the disabilities that remain with the patient for ever—the true "end-result disabilities" that so often spoil a good radiographic result. If every case were regarded from the first not simply as a fracture but as a soft-tissue injury complicated by a fracture there would be less danger of looking upon rehabilitation as a sort of salvaging process to be undertak the remote future. On the contrary, the attitude c surgeon should be such that conservation of functi the soft tissues becomes a major issue from the beginning. A wasted fibrotic muscle is not an a Providence and it cannot be cured by the laying c hands or any other mysterious process in the ph therapy department. It is as great a reproach to surgeon and a greater handicap to the patient th malunited fracture, because whereas the latter is a chanically correctible disability, the retrogressive cha that take place in neglected muscles are incurable once have passed a certain point. It is the responsibilit the surgeon to see that they do not pass this point du the period of immobilization.

Conservation Muscle Functi

Conservation muscle func during the pe of healing of fracture app both to the p that are immo ized and to th that are free to but are out functional use. few examples serve to illustr the principles volved.

1. In a "belo the-knee" plast (e.g., in a fractur dislocation of t ankle) the object a walking-iron is make the patient u his quadricep against the resi ance of body weigh which is infinite more effective f conserving the function than no weight-bearing exe cises of the kne joint. The cal muscles, however, are the real problem in these cases. The cannot exercise at all in a normal sense; but, even so, they nee not be regarded as out of the picture until the plaster is removed The synergic action of muscles should be taken advantage of. I the toes are actively and strongly dorsiflexed the plantar flexor of the ankle-joint immediately contract synergically. They d this in order to fix the ankle-joint, which would otherwis be dorsiflexed by the extensors of the toes; but the refle is so fundamental that they still contract even when the join is already fixed in plaster. If toe exercises are done strongl enough and regularly enough in such a case the synergi contractions of the leg muscles induced thereby will be suffi cient to prevent a good deal of wasting and fibrosis during immobilization. Similarly, in an arm plaster, if the finger are strongly flexed the extensors of the wrist go into synergic contraction, while strong extension of the fingers brings the flexors of the wrist into similar action. Yet how often are finger exercises, and especially toe exercises, neglected al together, or the plaster so badly cut that they are impossible? A very important point in these exercises is that they must be done strongly—gentle ladylike movements produce little synergic effect.

2. In a fractured femur the position is reversed. The ankle is free to move, though out of functional use, while

the quadriceps is only free to perform "static" contractions. These, however, must be done with the greatest regularity throughout the period of immobilization from the third week onwards. In regard to the "defunctioned" ankle-joint, this should not only be exercised through a full range of movement but it should be exercised against resistances comparable to weight-bearing stresses, thereby treating the leg muscles as one does the quadriceps in a "walking-plaster." Many text-books on fractures still reproduce photographs showing methods of supporting the ankle-joint in fixed dorsiflexion on a Thomas splint. This is entirely wrong. It should be free to move all the time, but its position of rest should be that of dorsiflexion. The simplest and most effective method of doing this is shown in Fig. 1: the weight in the bag is gradually increased so that during the whole period of splint treatment the patient is practising graduated resistance exercises for the calf muscles. No patient treated for fractured femur should ever have the slightest difficulty afterwards in regard to either the ankle-joint or the calf muscles.

3. In hyperflexion fractures of the spine conservation of function in the extensor muscles of the back is of paramount importance. Ankylosis in bad position gives a perfect functional result provided the muscles recover, but failure of these to recover always results in partial disablement for heavy work, however good the reduction and consolidation of the fracture.

These and similar measures for the conservation of muscle function require a great deal of co-operation on the part of the patient, and the surgeon or some responsible member of the fracture clinic team must be prepared to ensure that it is forthcoming. Ignorance, stupidity, apathy, and sheer laziness must all be overcome. In a fracture ward there are always a few good "workers" who can be disposed at strategic points where their influence and example will spread to less determined patients. Another asset is a ward sister who is more concerned with seeing that exercises are carried out than with keeping the bedclothes tidy. In out-patient cases instructional exercise classes must be held for those in plaster, and these patients must be thoroughly impressed with the necessity for carrying out their exercises assiduously at home. In fact, the more experience one gains in dealing with the later stage of rehabilitation the more one is impressed with the importance of these earlier measures. With good muscle recovery and an imperfect radiographic result there is always hope of complete functional recovery; but even if this does not materialize, operative correction still offers a chance of completely retrieving the situation provided muscle power is conserved. On the other hand, perfect radiographic results combined with atrophied fibrotic muscles end in disability that is permanent and irretrievable. It is no satisfaction to a working-man who cannot earn his living to know that his radiographs are being used to demonstrate the principles of accurate reduction.

Power and Mobility

At the Miners' Rehabilitation Centre the more one analyses disability the more one becomes convinced that the key to success is restoration of muscle power. Mobility is an advantage only in proportion to the power of the muscles to control it under the conditions of stress normally encountered at work. One has to think of plantar-flexion of the ankle, for example, in terms of pushing tubs of coal rather than in terms of walking across a floor. Muscles have two functions in regard to joints—they supply motive power in one direction and act as shock-absorbers and stabilizers in the other. This shock-absorbing mechanism is of great importance to miners and other working-men whose joints are subjected to great strain. If it is deficient the joint "gives way" under stress and a mild sprain is produced. Repeated traumata of this kind lead to chronic synovitis or even arthritis, which in their turn exert an inhibitory effect on the muscles so that a vicious circle is set up. That is why a patient who returns to heavy work with weak quadriceps complains that his knee swells at the end of the day and his leg does not get any stronger in spite of active use. It is also why traumatic arthritis is progressive, and the only rational treatment of the latter, therefore, is to strengthen the muscles that exercise a protective action on the damaged joint.

To a miner diminished mobility with full muscle power gives a much better functional result than full mobility with diminished muscle power. I have seen several instances of men with only 45 degrees of movement at the elbow-joint doing full work at the coal face while other men with 120 degrees of movement were unable to do so. Mobility, therefore, is not always an end in itself, and if muscles already weak have to be stretched in order to produce it, as in manipulative treatment they often are, the patient may be better off without the extra mobility.

Muscle-efficiency Tests

It is obvious that if muscle power is the key to success some method of measuring it must be adopted so that the value of different kinds of treatment may be assessed. This is done at Berry Hill Hall by expressing the power of a particular group of muscles as a fraction of the sound side. In the case of the extensor muscles of the back, which cannot be expressed in this way, a known standard is determined by testing normal subjects. The apparatus necessary to determine muscle efficiency is a system of pulleys and weights designed so that any desired movement can be isolated and performed against measured resistances. In the quadriceps extensor group, for example, the method employed is to load the sound leg till its "exercise tolerance" is reached. By this is meant the greatest weight that can be raised fifteen to twenty times in succession as an exercise. The same procedure is then repeated on the injured leg, and the result expressed as a fraction (e.g., $\frac{R}{L} = \frac{12}{25}$).

These muscle-efficiency tests have been carried out in a great many conditions, and the results are very instructive. For example, in compression fractures of the spine treated by reduction and ambulatory plaster for four to six months the efficiency of the extensors of the back is often as low as 20% after removing the plaster. This is so in patients who have done exercises throughout the period of immobilization. The results of these muscle-efficiency tests are charted week by week in the form of a graph, and constitute a very reliable guide to progress and to the value of different methods of treatment (Fig. 2).

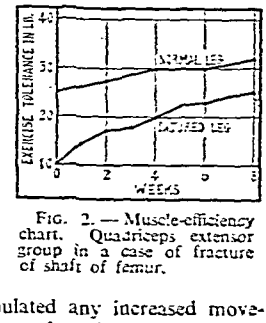

FIG. 2.—Muscle-efficiency chart. Quadriceps extensor group in a case of fracture of shaft of femur.

It becomes obvious at once why it is better to recover joint mobility by active movements alone. To do so ensures that muscle power increases with the mobility, so that the joint never recovers more movement than can be controlled under stress. In the great majority of cases stiffness after fractures is due to fibrosis in the muscles, and if such cases are manipulated any increased movement obtained is at the expense of tearing and stretching the fibrosed muscles. The charts of such cases reveal an immediate drop in muscle efficiency—often as much as 50%.

Manipulation should be avoided as far as possible, therefore, in those cases in which stiffness is due to

muscle fibrosis. Sometimes it has to be resorted to because the degree of stiffness is outside the limits of functional usefulness at work, and then the golden rule is to do a little at a time and repeat it every few weeks. If this is done the depression of muscle efficiency is minimal and the pre-manipulative level can be regained in a week or two. During the intervals the stretched muscles are treated daily. This treatment consists of active exercises to the limit of tolerance, deep massage to painful areas, and surging faradism. There is a second type of stiffness due to fibrosis and contracture in ligamentous or capsular structures, and this responds well to a full manipulation. The muscle efficiency in these cases is not depressed by the manipulation, and subsequent recovery is dramatic.

The Analysis of Functional Disability

The first essential in rehabilitation is an accurate analysis of the disability. The patient does not tell the surgeon which muscles are at fault; he expresses the disability in terms of function, and says what he cannot do or what he finds difficult or painful. In leg, back, and pelvic cases there is nearly always some disturbance of gait to analyse as well. Good analysis depends on a knowledge of the anatomy of function, which is not the way we learn anatomy. We are taught the action of isolated muscles instead of the muscle work of purposive movements such as walking, lifting, pushing, and so on. Yet without this knowledge it is impossible to analyse faulty gaits, obscure aches and pains, and difficulty in performing certain everyday acts. Still more impossible is it to analyse difficulty in performing complicated movements encountered in the course of heavy work. A patient may say, for example, that he can walk all right on the flat but finds difficulty in walking downstairs. This is common in quadriceps cases and is simply a question of mechanics. When the whole body weight is on one leg, the more the knee-joint flexes the more power is required on the part of the quadriceps to stabilize it, just as the load on an engine pulling a train round a curve is very much greater than when it pulls the same train along a straight track.

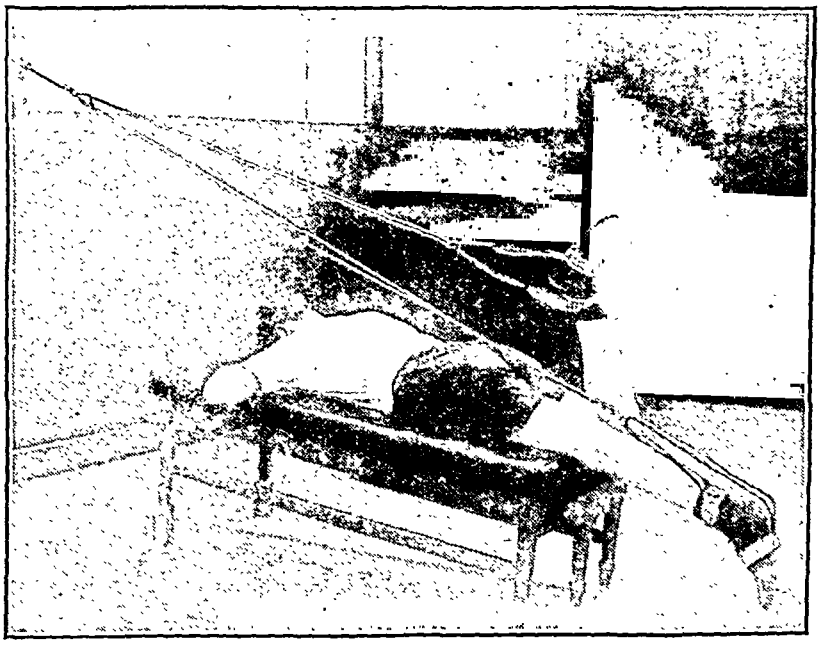

FIG. 3.—Mobility exercises: the auto-assistance principle

Lifting weights off the ground, which is vitally important to miners, is chiefly a gluteal action extending the hip-joints, but the spine must be fixed in relation to the pelvic girdle by a powerful static contraction of the sacro-spinalis muscles. It is failure of the latter that prevents miners from doing heavy work at the coal-face after a compression fracture of the spine; but the same functional disability might be due to a myofascial sprain of the gluteus maximus. All the miner knows is that he cannot lift the sort of weights he is called on to lift at work, and that efforts to do so are painful. Intelligent rehabilitation therefore depends on good analysis of functional disability, which in its turn depends on a knowledge of the anatomy of function and of the effects of trauma on soft tissues.

Remedial Exercises

Having analysed functional disability on these lines what is the remedy? What, in other words, is the secret of redeveloping weak muscles? The answer is that it can only be done by the unremitting efforts of the patient himself. Muscles hypertrophy only in proportion to the demands made upon them day after day and week after week. That is why professional footballers have such magnificent quadriceps, though their arm muscles may be quite ordinary. Exercises must therefore fulfil two conditions: they must be specific for the muscles concerned, and they must be progressive. The principle of progression is of the utmost importance in rehabilitation whether in relation to remedial exercises, occupational therapy, or games. Remedial exercises constitute the backbone of treatment, but they can only succeed if certain conditions are fulfilled. They must be performed day in and day out *ad nauseam*; they must be performed against gradually increasing resistances, and the periods of exercise must be correctly spaced with periods of rest so as not to induce undue fatigue. They fail in most cases because none of these conditions is fulfilled. The outpatient who attends an exercise class three times a week is rarely treated as an individual. He is a member of a "class" for back or leg or arm cases, and does the same exercises without progression from start to finish. Moreover, he seldom exercises during the intervening periods, through lack of instruction to do so, lack of self-discipline, or gradually increasing apathy as his disability drags on.

At the Miners' Rehabilitation Centre remedial exercises are carried out in the gymnasium for two periods of an hour and a half each day. They are arranged into a series of progressive schemes for each type of case, and are under expert supervision. In a back case, for example, there are four schemes, and it takes the average patient eight weeks to work through them. It is outside the scope of this paper to describe remedial exercises in detail, but one or two points are worth special mention. The first is in regard to a type of assisted active movement in which the patient himself provides the assistance with the opposite limb. It is illustrated below for flexion of the knee (Fig. 3). This type of mobility exercise is specially useful (*a*) when unassisted active movement is painful (this is frequently the case in shoulder injuries, or after a manipulation); and (*b*) when unassisted active movement is not powerful enough to make any headway

against the resistance imposed by the fibrosed structures causing the stiffness.

I know that passive movements are nowadays condemned, but many of these patients would never make any headway without some assistance. I differentiate between passive movements and assisted active movements, however, and, provided the assistance is given by the patient, it can do nothing but good. Relaxation of the opposing muscles is the crux of the matter, and to obtain this the patient must have perfect confidence. If a second person is providing the assistance the patient instinctively puts the brake on long before the limit of tolerance is reached, because any other method of informing the operator that he is approaching this point would be too slow to act in time. With the patient himself in control, however, perfect relaxation is possible right up to the full limit.

The second point is in regard to graduated resistance exercises, which are extensively used for selective strengthening. The principle is best illustrated by the hypertrophy of involuntary muscle. If the intestines or the bladder have to work against a gradually increasing obstruction they invariably hypertrophy—often to a remarkable degree. The two factors which produce this hypertrophy are a gradually increasing resistance and a muscle acting almost continuously in an effort to overcome it. If the load is increased too suddenly, however, failure occurs. These factors apply equally to voluntary muscle, and the more difficult the case the more gradual must be the progression. The muscle-efficiency chart is the real index of progress.

To give graduated resistance exercises the same pulley-and-weight apparatus described earlier for measuring muscle efficiency is used. It can be applied to any muscle group in the body, but to illustrate the method the quadriceps extensor group will be used as an example. First of all the exercise tolerance of the affected muscle is determined—that is, the greatest weight the patient can raise with his quadriceps fifteen to twenty times in succession. At regular intervals, depending on the individual factors, half a pound is added, often without the patient's knowledge. He can work with these maximum loads for only very short spells, so the method followed is to intersperse these with more prolonged exercises against 50% of the maximum load. By this method satisfying results have been achieved in the most unpromising cases. As an example, it has been found possible to increase the quadriceps efficiency from 4 lb. to 26 lb. (normal leg, 32 lb.) in an old-standing case of a man who had been off work for two years following a knee injury.

Accessory Methods

The other forms of treatment used, which make up the rest of the six-hour day, are occupational therapy, physiotherapy, and remedial games. These are accessory methods, however, and it is fallacious to think of rehabilitation entirely in terms of one or the other, as a good many people nowadays do. Indeed, this seems to be the official conception of rehabilitation. At Berry Hill Hall we rely on remedial exercises to gain ground, and on occupational therapy and remedial games to consolidate it. The idea of adding creative interest on the one hand or competitive interest on the other is very sound and attractive, provided such ideas are not allowed to become a hobby-horse and obscure the essentials underlying them. The weakness of both is that neither the principle of selectivity nor the principle of progression can be so scientifically applied. Furthermore, none of the forms of occupational therapy in standard use would get a miner anywhere near the stage of full work.

Occupational Therapy.—It is impossible in the limits of this paper to deal in detail with the application of occupational therapy or remedial games to particular injuries, but a brief description of both as organized in a rehabilitation centre may indicate their general usefulness. Occupational therapy is divided into indoor and outdoor work. The men at Berry Hill Hall assist in the laundry and do all the domestic cleaning in the gymnasium. In the craft-room the hand and arm cases are taught to make wicker-work baskets, trays, and stools, and leg cases to do treadle work. The remedial workshop is equipped for simple carpentry, and a miniature conveyer-belt has been installed which gives the back cases an opportunity of practising the movements and experiencing the stresses peculiar to their own work, but under controlled and progressive conditions. The belt runs over spindles operated by cranks, and motive power is provided by the advanced arm and shoulder cases. The action is like that of turning a mangle, but it is a progression on laundry-work. Logs of wood weighing from 10 lb. to 80 lb. are used instead of coal. Outside in the grounds of the estate there are gardening, timber-work (tree-felling, log-sawing, etc.), and the care of lawns, cricket pitch, tennis court, bowling green, etc. Each patient is scheduled to a class of work suitable for his injury, and as he makes progress in his gymnasium work he is correspondingly advanced in occupational therapy.

In addition to these forms of occupational therapy, some of which (e.g., timber-work) are quite heavy, I am able to use the enormous resources of the industry in placing men at a variety of jobs in the pits which can be used as a very advanced form of occupational therapy. Most back cases, for example, are sent to a period of "datalling" work, which involves a good deal of walking, bending, shovelling, and lifting, but allows the workman to pause occasionally between efforts instead of going "all out" all the time, as he would have to do at the coal-face. A knowledge of industrial processes is needed to place men properly if light work is to be successfully used as a remedial agent, and it is necessary to keep contact with such cases. Periodic re-examinations are therefore made till they either resume full work or have otherwise reached the limits of progress and been placed in the class of permanent light work most suitable for them.

Recreational Activity.—This also takes indoor and outdoor forms. Many games can be played in the gymnasium, but there is much more scope in the open air. Games such as badminton, bowls, croquet, etc., are played for amusement after the day's treatment has finished. During the official games period, however, the men are supervised in their activities and the games are more adapted and remedial. Back cases do particularly well on games like basket ball and tunnel ball. Leg cases, however, have to be carefully watched if they are allowed to play running games, otherwise a considerable number of sprains will be incurred, especially if there is a football about. This is because the muscles of these patients are not efficient enough to protect their joints against the sudden twists and strains of vigorous games. Leg cases are sent out in groups on bicycles, which is one of the most excellent of all forms of recreational activity, and many patients living within five miles or so of the centre cycle in every morning as part of their treatment. As in occupational therapy, recreational activity must also be progressive and adapted to the injury, and there is infinite scope for originality and ingenuity in the invention of new games to promote particular movements.

Physiotherapy.—Physiotherapy is confined to faradism and deep massage. The former is used as an auxiliary method of strengthening weak muscles; the latter in dealing with painful areas in muscles. These are quite

common following trauma, and they inhibit full active use of the muscle so that the patient is never able to get the maximum benefit from remedial exercises. They are due to localized fibrosis in areas to which traumatic exudates have gravitated. Deep massage is very effective, but it must be done properly—skin-stroking is useless. Preliminary injection with 2% procaine just below the muscle aponeurosis is helpful in many cases. Once the pain is abolished there is a dramatic increase in muscle power, showing that this was there all the time but was inhibited by the pain. In the analysis of disability referred to earlier it is important to distinguish this type of case from the one in which loss of power is due to atrophy alone, since the treatment is quite different.

Summary and Conclusion

In this paper the principles underlying the process of rehabilitation have been described. The final stages of this process are best carried out in special centres, but the earlier measures directed towards conservation of muscle function during immobilization are of equal importance.

The methods of treatment employed in a rehabilitation centre for injured miners are described. This centre was established by the employers of 100,000 workmen, the accident rate amongst whom is five times greater than the average accident rate in industry.

The only criterion by which success in rehabilitation can be judged is the patient's return to full pre-accident work and activity. Clinical attempts to assess this are unreliable. In a consecutive series of 1,200 patients treated in one year in the Mansfield Hospital Fracture Clinic, all of whom were miners injured at work, 87% resumed their full pre-accident occupation, and 9% resumed lighter work in the same industry. There was a mortality rate of 1%. In about 15% of the mining accidents dealt with in this clinic treatment is completed at the Miners' Rehabilitation Centre.

The Central Council for Health Education is able to command the services of some most talented people with the pen, pencil, and camera, and some of its leaflets, which are sold at production cost to local authorities and distributed in various ways by medical officers of health, are as telling as the very best commercial advertising. Three pictorial leaflets bearing the titles "Ears to Hear," "Eyes Right," and "Sleep" convey their message in a series of film-like pictures which make words largely unnecessary. A number of posters have also been brought out by the Central Council, and are so emphatic in their design and colour that he who runs may read. For those who may prefer to do their reading while not running there are a number of pamphlets on such subjects as the prevention of diphtheria, the war on lice, the elementary facts concerning milk, food, water, and sanitation, which lack nothing in the directness of the advice they give. A whole series of leaflets has been prompted by war conditions. Among them is a 16-page booklet on "Health in the Shelter," in which the clever levity of the drawings relieves the necessary seriousness of the text. It is the aim of the council to secure that every possible subject connected with health on which the public ought to be informed shall be illustrated by a popular leaflet or pamphlet. The war has opened up quite a number of new subjects, of which "Health in the Black-out," the title of a new leaflet, is one. The attractive booklet, "The Doctors tell you what to eat in Wartime," which was prepared by the British Medical Association at the request of the council, is another example of activity in this direction. It is suggested that some of these leaflets might be placed on the table in the waiting-rooms of medical practitioners. Medical practitioners, however much it may be against their mundane interests, are amongst the best apostles of preventive medicine, and we do not doubt that many of them will accept the invitation of the Central Council (whose address is Tavistock House, Tavistock Square, W.C.1) to have a free supply of this health publicity material sent to them for this purpose.

PULMONARY CONCUSSION ("BLAST")

BY

G. R. OSBORN, M.B., B.S.Melb.

Pathologist, Derbyshire Royal Infirmary and Derby City Hospital

"Every new ordeal to which the lung of man is exposed produces if not an entirely new lesion at least a new angle from which to study an old one."—LANCET.

"Pulmonary concussion" is a term which has been used for haemorrhagic lesions of the lungs resulting from the detonation of high explosive. Cases are recorded here which show that virtually the same syndrome can be brought about by the ordinary forces of civil life as by the action of bombs.

Experimental and theoretical considerations have now established beyond reasonable doubt that blast injuries of lungs are produced by the high-pressure wave of the blast acting for a short period; in other words, it is due to a sudden diffuse compression of the lungs through the chest and abdominal walls, and is typically unaccompanied by obvious injuries of the thoracic wall. "Diffuse" does not mean that the two lungs are equally affected, just as injury to the thoracic wall does not exclude the action of blast. A sudden diffuse compression of the lungs can readily be brought about by mechanical causes. More important under war conditions is the fact that the compression of blast and of mechanical forces frequently occur together. The most important difference between war and civil cases is the greater degree of violence in the former.

Comparison of Peace and War Injuries to the Lungs

I have notes of 94 necropsies made during the last three years on persons dying through road accidents. In reviewing these it is notable how many ribs may be fractured with no lung injury at all: 6 cases, all those of men between 58 and 69, had multiple rib fractures but no lung damage. Four more had multiple rib fractures and minor lacerations of the lungs from the rib ends, but no appreciable contusion of the lungs; these cases were those of a boy aged 13 and three men between 39 and 44. A man aged 21 showed lacerations and pulping of the lungs after an aeroplane crash. Three patients with fractures of the skull inhaled some blood; these were males aged 10, 13, and 19. Only 3 of the 94 had lung lesions comparable to those of the bomb cases; these were in girls aged 4 and 8, and a boy of 7. The best example is a girl of 4. A motor-lorry had run over her and caused a fracture-dislocation of the sixth and seventh cervical vertebrae, but no fracture of or external mark on the trunk. Her lungs showed multiple haemorrhages, which all appeared on the pleural surface; they were most numerous in the parts of the lungs which enter the phrenico-costal sinus of the pleura and posteriorly, but there was some rib marking on the lateral surfaces. The liver showed a small laceration of the posterior surface and there were some peritoneal tears in the transverse colon. The girl of 8 had been knocked down by a motor-car; she showed a little bruising over the left lower ribs but was otherwise unmarked; the ribs were not fractured. There was a haemothorax of nearly two pints on the left and a smaller one on the right. There was a large tear near the hilus of the left lung, and contusions were scattered fairly generally throughout both lungs. The liver was torn but the spleen was not. The boy of 7 was run over by a motor-lorry. He sustained an extensive fracture of the skull with brain injury. The trunk was not marked. The left lung showed a widespread haemorrhagic lesion about the hilus posteriorly, "rib markings" extending about three-

quarters of an inch deep, and a wedge-shaped contusion of the part in the phrenico-costal sinus. The right lung revealed innumerable haemorrhages the size of a pin's head, due to inhalation of blood from the left; the spleen showed a little superficial bruising only. The brain injury indicates that death must have been very rapid.

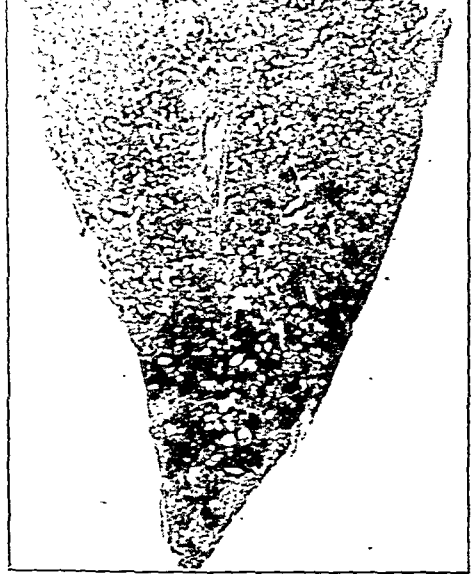
Lung injuries were therefore present in only 8 of the 94 cases. Of the 8 cases 4 were simple lacerations from fractured rib-ends and one was too gross to be of interest. The 3 most important cases were in children with flexible chest walls, and both were accompanied by abdominal injuries. The series does not include any case of compression asphyxia, but, looking through the series of asphyxial cases (suicidal hanging, homicidal strangulation, overlain babies, and babies born face down on to the placenta in a bucket), it is notable how inconstant Tardieu's spots are. My experience is the same as that given in Taylor's *Medical Jurisprudence* (1928), and does not agree with Ross (1941) that they "are nearly always found." They are interesting if found, but are so frequent in diseased conditions that they cannot be made a prominent part of any syndrome.

The four most interesting contusions of the lung did not occur in road accidents; they were described under the title of "phrenico-costal sinus pneumonia" (Osborn, 1940). The review of the road and bomb cases serves to emphasize the point made there that there is an abdominal component to the force which produces the basal contusion of the lung. If this wedge-shaped lesion is present the question is not "Is the underlying spleen or liver damaged?" but "How severely is it damaged?" It may be a trivial bruise or a hopeless tear.

The first 8 cases described below were from bombed houses.

Case 1.—A girl aged 17. Fractured skull the only external injury, no bruises or fractures about the chest or abdomen. The lungs showed a large wedge-shaped haemorrhage at the left base and a much smaller one at the right base; a fairly large haemorrhage into the posterior part of the right mid-lobe; haemorrhages posterior to the hilus on each side; and some small pleural haemorrhages laterally which were possibly "rib markings." Most of the haemorrhages reached the pleural surface. The upper pole of the spleen showed multiple tears; the liver and other abdominal organs were undamaged. This girl had blood-stained mucus and froth in the large air passages.

Case 2.—A woman aged 42, mother of the previous patient. She was beside her daughter when the house was hit, and also had a fractured skull. The upper three left ribs were fractured and the lung showed contusions in this region only; small haemorrhagic spots elsewhere were probably due to inhalation of blood. The lung changes in this case were very mild compared with those of the daughter; this may be because the mother was obese. She had no abdominal injury, and lived for about twelve hours after being hurt.



Case 3.—A girl aged 16 had multiple injuries which included pieces of wood driven into the trachea and left lung. There were scattered small haemorrhages throughout the lungs; a large one into the base of the right lung was accompanied by a ruptured liver beneath. The right hand and forearm had been blown off.

Case 4.—A young unidentified woman who was too mutilated for lesions to be instructive.

Case 5.—A man aged 40 who had a compound fracture of the skull but no injuries to the chest or abdomen.

Case 6.—A woman aged 40, wife of the previous patient, average size, not obese. There were large numbers of punctured wounds over the exposed parts of the body (head, neck, arms, and legs); with few exceptions these were superficial and did not contain foreign bodies. The largest were in the right supra-scapular and supra-clavicular regions; through the latter the axillary vessels had been pulped. This injury was of interest because it was evidently the place where a collection of dirt particles measuring 1 by 0.3 by 0.3 cm. had entered the vein to lodge in the right ventricle, the heart itself was not damaged. The skull showed four perforations about 1.5 cm. in diameter in the frontal and parietal regions; bone had been driven into the cerebrum through two of these. Both orbital plates of the frontals were fractured upwards, with orbital contents projecting through; there was no injury about the eyes to account for this. The base of the skull was not damaged otherwise, but there was haemorrhage into the middle and internal ear on the left side. The chest was free from external marks, but the upper four right ribs were fractured posteriorly at their angles; these had not caused any laceration of the lung. The right apex showed a healed tuberculous focus 1 cm. in diameter, the left apex a smaller lesion. Old adhesions were present over the right upper lobe and the left apex. The right pleural cavity contained half a pint of blood, the left none. Much blood and mucus (not frothy) were present in the trachea and large bronchi. There was a massive haemorrhagic lesion of nearly all the right upper and mid lobes; the right lower lobe was normal. Scattered throughout the left lung were very large numbers of small haemorrhagic spots due to inhalation of blood from the right side (see below). No pleural haemorrhages were observed on the left side. There was no phrenico-costal sinus lesion and no injury to the abdominal organs. This woman lived three hours.

Case 7.—A woman aged 26, of average size and nutrition. There was a perforating wound of the left chest posteriorly about the inferior angle of the scapula. A bomb splinter

Phrenico-costal contusion (Case 7). Photomicrograph (× 3) of wedge-shaped haemorrhage into base of right lung. The clear parts in the dark haemorrhagic zone are mostly distended alveolar ducts and small bronchioles. This lesion always suggests laceration of the underlying liver or spleen

weighing 2.5 grammes had passed through the seventh rib here, through the left lung in the interlobar region, through the anterior part of the pulmonary artery and the right cusp of the pulmonary valve, and had come to rest in the right ventricle close to the tricuspid valve without doing any damage in the ventricle. There was free haemorrhage into the lung along the path of the bomb fragment and also posteriorly; the left base was practically clear. The right lung was normal except for a perfect example of the phrenico-costal sinus contusion (see Fig.). This was placed laterally and posteriorly, was wedge-shaped, and measured 7 cm. from

front to back, 4 cm. upwards, and about 3 cm. deep at the upper part, which was appreciably raised from the surrounding normal lung on the pleural surface. This haemorrhage was firm, but lacked the almost stony hardness of the lesion in the civil cases which survived some days. There were multiple tears of the liver, tears of the upper pole of the spleen, and a superficial tear of the upper pole of the left kidney.

Case 8.—The 7-months-old baby daughter of the previous patient. She had a depressed fracture of almost the whole of the left frontal bone with brain tissue protruding around it. There were no other marks of any sort on the body. The lungs showed very distinct haemorrhagic rib markings laterally on each side; these became confluent in several places, notably the posterior portion of the right lung. In parts the rib markings extended a full centimetre into the lung, and were separated there, as on the surface, by clear lung tissue. All haemorrhages in these lungs were represented on the pleural surfaces. The only haemorrhages not related to rib markings were on each side in the part of the lung that enters the phrenico-costal sinus. These were not relatively as large as the wedge-shaped lesion in Case 7, but were associated with several tears in the liver. The abdominal organs were otherwise normal.

The following two very recent cases, which have a bearing on the mechanism of production of the lesions, may merit a brief note.

Case 9.—A girl aged 11 collapsed under an anaesthetic of open ether just as an operation for the removal of an acutely inflamed appendix was being completed. As she did not respond to the usual methods an upper abdominal incision was made and the heart was massaged. The auricles started beating, but not the ventricles. At necropsy she appeared to have been a healthy girl. She was deeply cyanosed; the blood was dark and fluid. There was extensive bruising of the ventricular muscle from the massage. This bruising was not beneath the pericardium, where the direct force had been applied, but was a very short distance from the endocardium. The endocardium was not injured. The bruising appeared to have been produced by the reactionary force of the compressed blood.

Case 10.—A baby girl aged 15 months was brought to the Infirmary moribund; she had inhaled a piece of bean four hours previously. This blocked the left main bronchus and part of the right. When seen by the casualty surgeon she had stopped breathing, but the heart could be heard beating infrequently. Artificial respiration was applied, but failed to revive the child. At necropsy the left lung was seen to be collapsed, the right partly collapsed. Very small numbers of Tardieu's spots were present, but haemorrhagic rib markings beneath the visceral pleura were quite distinct, especially over the left lung. The rib markings were very shallow when compared with cases from the bombed houses. They were probably produced by the artificial respiration, and were more noticeable on the left side because the left lung was extensively consolidated while the right still contained some air.

Microscopical Features

Two main types of lesion are seen microscopically. In the primary and larger haemorrhagic lesions there is free haemorrhage from the alveolar capillaries, while the alveolar ducts and bronchioles are typically air-containing and almost free from haemorrhage. The larger bronchioles and small bronchi in the worse lesions—e.g., the right lung of Case 6—give good evidence of compression of the lung from without. They are collapsed, and practically all the goblet cells in the mucosa have been ruptured, causing a stream of mucus to flow into the bronchial lumen; with the mucus is a little blood but very little air. The mucous glands and the basal, intermediate, and ciliated cells of the bronchial mucosa are little affected compared with the goblet cells. Incidentally this shows well how much mucus is available from goblet cells alone to make the bronchial mucous plugs of the influenzal lung. The relative scarcity of goblet cells in that part of the lung which enters the phrenico-costal sinus may account for the difficulty in recognizing this lesion in the wedge-shaped haemorrhages there. Rupture of goblet cells appears to indicate severe lung damage. Distension of alveoli with blood or air (emphysema) regularly accompanies compression haemorrhage, and subpleural bulla formation is fairly common.

The second main type is the result of inhaled blood, and is apt to be mixed with the previous type. Blood is present in the small bronchi of the affected region, and distension of alveoli is not usually as marked. Typically this lesion is relatively small and scattered, and in my cases has been accompanied by much more serous exudation in the surrounding alveoli than is seen in the compression haemorrhage. Goblet cells are, of course, not ruptured.

Is the Haemorrhage Progressive?

Hadfield and Christie (1941) state that they regard the haemorrhage in these cases as being progressive and that "in reviewing a series of post-mortem examinations of 17 of these cases we have been struck by the variability in extent of these haemorrhages, and it appears reasonable to relate this variation to the period of survival after exposure to detonation." With these statements I am quite unable to agree. The haemorrhagic lesions themselves are not necessarily fatal, though it is easy to imagine rapid death from shock. The most probable reason that their patient lived fifty-one hours is that the abdominal component appears to have been confined to submucous gastric haemorrhages. There are too many unknowns in my cases as well as in those described by Hadfield and his colleagues (1940) to imagine that we can correlate the extent of the lesion with the period of survival. Of these published cases the period of survival was known in only 4 out of 19, and though the notes of 2 are scanty it would appear that 3 out of the 4 patients who survived some time were not as badly affected as some who died more rapidly. The probable reasons for more severe lung lesions are the severity of the causative force and the state of the patients. By the state of the patients is meant whether they are obese or not, whether they have flexible or rigid chest walls, whether their lungs are in the position of inspiration (making it worse) or expiration at the time of injury, and the amount of clothing worn by the victim. It is the state of the patient which explains why these cases did not attract attention during the last war. The potential victims then were grown men wearing a respirator, knapsack, and other things which would protect their body walls from the impact of the blast wave; now we are seeing unprotected girls and children attacked by bombs in confined spaces. Some direct evidence can be given indicating that the haemorrhage is not progressive. First, the haemorrhage is into alveoli which are arranged in limited groups. Only a little of this blood gains access to a bronchus to reduce the raised pressure due to the haemorrhage. Secondly, the haemorrhage is from capillaries. Capillary haemorrhage typically ceases within about five minutes and requires only a slightly raised pressure to stop it. Thirdly, the cases of "phrenico-costal sinus pneumonia" seem to prove that the bleeding is not progressive. The wedge shape, size, and raised pleural surface laterally and cranially are similar in the cases of bomb injury and in the patients who survived for two and seven days. In the last two cases the most advanced organization was at the upper end of the lesion near the unaffected lung tissue: here the alveoli showed much more fibrin, and phagocytic cells were more active. There was no evidence of more recent haemorrhage at the upper limit of the lesion, and the best-preserved red cells were in the centre of the lesion, where it appeared that resolution would take longest. For these reasons I believe that the primary lesion is not progressive, but the reaction to the lesion may make it appear to be so, especially in *x*-ray plates.

Mechanics of Haemorrhagic Concussion of the Lungs

Reasons for believing that the lesions are due to the high-pressure wave of the blast acting on the body wall and not to positive or negative pressures acting through the trachea and bronchi are given by Zuckerman (1940), and need not be repeated. Additional proof is given here by (1) the mechanics of "phrenico-costal sinus pneumonia" (Osborn, 1940), and (2) the goblet-cell lesion and collapse of the bronchi in the worse cases.

Zuckerman (1941) goes to some pains to belittle the effects of blast unless the victim is very close to the bomb, and states that there have been very few cases of blast injury of the lungs in England so far. Lung injuries having the features described by Sir Joseph Barcroft (1939) and by Zuckerman in animals are now only too common in hospital practice. An attempt has been made here to show that the same lesion may result from a sudden diffuse compression of the chest and abdomen by bombs and mechanical means. Whether the lesion is entirely due to blast or not seems to be of little more than academic interest. Zuckerman may be correct when he says that there is little danger from blast more than thirty feet away from the explosion of a big bomb in the open, but there is no justification for belittling the effects of blast in confined spaces such as houses. We have no means of telling what blast pressures the victims in houses were exposed to: the positive pressure there cannot fall until free access to the outside air is obtained. There is also no justification for his statement that "at sixty or seventy feet the pressures did not really matter at all clinically, even though they might be sufficient to damage walls and windows" and "throw a man against a hard surface." Zuckerman's statement is usually true just as it is usually true that if we fall over we will not die of "phrenico-costal sinus pneumonia": in each case, however, it is how the violence is applied that matters, and the unusual in each case may be common in medical practice if sought after.

What is the force which actually brings about the capillary haemorrhage in haemorrhagic concussion? Two forces have to be considered. These are the compression of the lungs through the chest wall and diaphragm and the counter-pressure exerted by the air in the alveoli. When danger threatens it is instinctive for the muscles to go "on guard": this includes spasm of the glottis more or less locking the air in the lungs. The high pressure produced in this alveolar air by compression is the most likely force which ruptures the capillaries. This explains why the haemorrhages are deep and often massive; it may also help in understanding their distribution. In my cases this type of haemorrhage has mostly occurred in young adults and has not been associated with rib markings. Haemorrhages from the primary force are likely to be found in cases in which reflexes are not well established—e.g., in small babies and experimental animals. Thus Case 8 is a perfect example of haemorrhages produced by the ingoing ribs, etc., in a baby of 7 months. Other cases—e.g., Case 1—show a combination of both types of force. The findings in the baby's case certainly do not support Ross's (1941) statement that rib markings are a feature of "compression asphyxia" in which "death has presumably been slow, with attempts at respiration": at least I am sure that this baby died quickly. I cannot see how Ross correlates Sir Joseph Barcroft's and Zuckerman's findings in pure blast injuries of animals with her statement that "in haemorrhagic concussion the lesions are always bilateral and roughly symmetrical. There is general congestion of the lungs. Pleural haemorrhages are present only as an extension from deeper areas." Rib markings were the main findings in goats: "These lesions consisted of bruising of the surface of the lung in the line of the ribs and vertebral borders, and extended for one-quarter to half an inch into the tissue of the lung": this is also a description of the baby (Case 8). Zuckerman showed that one lung might protect the other if the animal was placed side-on to the explosion: this apparently is more likely to happen if the animal is fairly close to the explosion. To understand the lesions described for blast in animals and man there is no need to assume that blast has any mysterious properties: it is only a more severe diffuse sudden compression of the chest and abdomen than we see in civil cases during peacetime.

Main Clinical Features of Pulmonary Concussion

The great majority of cases so far reported have come from bombed houses and shelters: pulmonary concussion appears to be infrequent in cases injured in the open. In houses it takes longer to dissipate the high-pressure wave of the explosion, and mechanical factors are likely to be added to the blast effects. Pulmonary concussion should be looked for in every case from a bombed house.

Factors tending to minimize pulmonary concussion are advancing years, obesity, rigidity of the chest wall, the position of expiration, and thick clothing. Pulmonary concussion may take a number of forms, which depend on the state of the patient as much as on the degree of violence. The younger the victim the more probable is it that the haemorrhagic lesions will be subpleural ("rib markings"). Young adults usually have deeper haemorrhages. Much mucus in the air passages (with blood) indicates that goblet cells have been ruptured in the bronchial mucosa; this means that the lungs are severely affected.

So far too little attention has been paid to the fact that the abdomen is suddenly compressed as well as the thorax. The wedge-shaped lesion of the part of the lung which enters the phrenico-costal sinus of the pleura is of exceptional importance because it indicates with a high degree of probability that the underlying liver or spleen, or both, have been torn. If these tears are severe the victim will be found dead; doubtless some will be amenable to surgical intervention. In my small series the liver and spleen were affected much more often than the bowel; bowel tears were confined to the peritoneal surface and would have needed no treatment. Should operation ever be indicated the organ responsible for the abdominal haemorrhage is likely to be demonstrated by the side of the phrenico-costal sinus lesion. If this is placed posteriorly as well as laterally on the right side the tear in the liver will probably be inaccessible. Tears of the spleen are likely to be at the upper pole.

Pulmonary concussion is not necessarily fatal. Sir Joseph Barcroft found that his goats usually recovered if they were not killed rapidly; Zuckerman also found his smaller animals tended to get better. It is worth recalling that in one of my cases of "phrenico-costal sinus pneumonia" death resulted from acute pulmonary oedema after two days, and in another case death occurred from pulmonary embolism after seven days. The latter cause of death is preventable: it is due to stasis in the femoral veins allowing the formation of clot, which becomes detached after about a week and is then carried to the right heart and pulmonary artery. Pulmonary embolism is prevented by regular active movements of the lower limbs aided by raising the foot of the bed to prevent haemostasis and by avoiding dehydration and other causes of haemoconcentration. If the patient does not die soon death may result from complications such as these, and probably the most important thing in treating haemorrhagic concussion of the lungs is to anticipate and so prevent such complications.

A "very clear history of the incident" cannot be obtained by the clinician, and its importance in diagnosis and treatment has been much exaggerated. It is of great value to know that the case is from a bombed house or shelter, and this is nearly always known. With this knowledge the most accurate diagnosis of the state of the lungs will be made by a consideration of the state of the patient (see above) and not from a knowledge of the size of the bomb. The peculiar behaviour of blast on houses is now so familiar (e.g., I have seen a shop window within six feet of a bomb crater in the road with only a single crack) that it is just as likely as not that the clinician would be misled by a "very clear history of the incident." The clinician will not be misled if he applies sound clinical methods, which should include repeated radiographs, if possible, and special attention to the phrenico-costal sinus region.

The knowledge that the case has occurred in a confined space will also help the clinician if he keeps in mind the important observation of Hadfield and his colleagues that these patients are prone to suffer from carbon monoxide poisoning.

Summary

Cases of pulmonary concussion from civil life and bombed houses have been compared.

Pulmonary concussion is almost the rule in cases from bombed houses, but not from bomb injuries in the open.

The mechanism of the lesion is considered. In bombed houses mechanical factors may add to the effect of the blast pressure.

The state of the patient is probably of greater importance than the size of the bomb or the distance from it. Knowledge of the details of the bomb may be misleading. In houses the positive pressure cannot fall until walls and roof are blown open.

The actual lesion is mainly haemorrhage from alveolar capillaries. Only a little blood gets into the bronchioles, etc., in these parts. Rupture of goblet cells and liberation of much mucus indicates a severe lesion. Secondary inhalation of blood gives a different picture.

Certain parts of the lungs are predisposed to injury. Thus we find subpleural "rib markings," injury in the phrenico-costal sinus region, and deep and posterior lesions in the region of the hilus. A consideration of primary (compression) and reactionary (counter-pressure of air locked in alveoli) forces may explain differences.

The abdomen is typically compressed with the thorax. The most important lesions here are tears of the liver and spleen.

The lesion itself is not progressive, but the reaction is. Treatment is largely anticipation of complications. The usual methods of artificial respiration may cause pulmonary concussion.

I am indebted to Detective-Sergeant J. S. Fayers for the photomicrograph

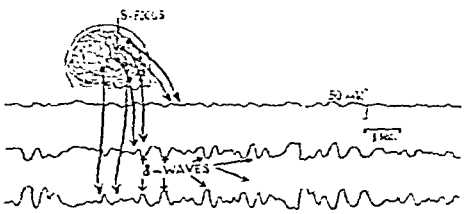
The London Hospitals Street Collections Central Committee (36, Kingsway, W.C.2) has issued a leaflet with reference to Hospitals Day in 1941, which includes a message from the Patron, H.M. the Queen. As in 1940, all participating hospitals will have the opportunity of collecting both in May and in October; the dates chosen are Tuesday, May 6, and Tuesday, November 7. A list is given of the hospitals co-operating and the amount received by each from last year's combined street collections, which totalled over £46,000.

ELECTRO-ENCEPHALOGRAPHY IN TRAUMATIC INTRACRANIAL HAEMORRHAGE

BY

LAMBERT ROGERS, M.Sc., F.R.C.S.

Surgeon Captain, R.N.V.R.; Professor of Surgery in the University of Wales, and Consultant in Neurosurgery to the Royal Navy



Electro-encephalography is becoming more and more important in the detection of various intracranial lesions, and Berger's contention that the phenomena which he described would afford a means of diagnosing certain pathological conditions of the brain may be said to have been generally upheld. So far, however, electro-encephalography has not been used to any extent in the investigation of cases of head injury; consequently it would appear desirable to record such evidence as may be obtained concerning its value in these cases, particularly when intracranial haemorrhage has occurred. Records from cases of traumatic intracranial haemorrhage are conspicuously few. In this country Prof. Rendle Short and Miss Dunster (1940) have published the findings in the case of a patient aged 42 with a middle meningeal haemorrhage upon whom operation was successfully performed. A tracing from a case of chronic subdural haematoma in an Italian aged 41 is included in a paper on electro-encephalography by Balado, Romero, and Noiseux (1939) of Buenos Aires; and some examples of intradural haemorrhage, both extra- and intra-cerebral, have been noted by Jasper, Kershman, and Elvidge (1940) of Montreal. The case here noted is a further instance of an encysted subdural haematoma following head injury which at the time of operation presented singularly few symptoms.

Case Report

On July 24, 1940, a marine aged 20 was knocked out in the boxing ring, and on regaining consciousness a few minutes afterwards had a severe headache. An hour later he vomited. He did guard duty that night, however, and was able to go out on a route march next day. His headache, which was now chiefly in the left frontal and occipital regions and at times was accompanied by pain in the back, continued, so he reported sick and was admitted to hospital. There was neck rigidity at this time, his temperature was 99° F., and his pulse was consistently slow (48 to 50). Both optic disks were blurred; the tendon reflexes were normal and the plantar responses flexor. Leucocytes numbered 10,000 per c.mm., *x*-ray examination of the skull was negative, and the cerebrospinal fluid pressure in the lumbar pond was 250 mm. of water; the fluid itself being deep yellow in colour, with a protein content of 120 mg. per 100 c.cm. The chief symptoms now were headache and photophobia, but these got better as he rested in bed. On August 29 Surgeon Captain Macdonald Critchley and I were called in to see him. He was inclined to be fatuous, the left knee-jerk was brisker than the right, and the left plantar response was extensor. High papilloedema with exudates and retinal haemorrhages was present in both optic disks. On September 24 Mr. W. Grey Walter, to whom I am much indebted for the tracing (see Fig.), carried out electro-encephalography at the Burden Institute under the direction of Dr. Golla, and reported: "There is a very low potential discharge at varying frequencies in the right fronto-temporal region, most definite in the neighbourhood of the Sylvian point. The small size and irregular frequency of this discharge would suggest that it is vestigial and not associated with any active destructive process." On September 7 the patient felt quite well, was free from headache, and declined operation. The highly choked disks, however, were still present, and, because of these and the slight left pyramidal signs and the electro-

encephalographic findings, it was considered that he had a chronic subdural haematoma overlying the right cerebral hemisphere.

Operation.—Operation was carried out on October 3, a right subtemporal craniotomy, being performed under pentothal-nitrous-oxide-oxygen anaesthesia. When the dura was

Electro-encephalogram in a case of traumatic intracranial haemorrhage (subdural) in a man aged 20

opened a blood cyst was exposed, occupying the Sylvian fissure and overlying a large area of the cortex. Part of the cyst wall was removed and its contents were evacuated by washing with Ringer's solution and by suction through small soft rubber catheters. The cerebrum was flattened and depressed beneath the cyst, but gradually expanded to take up the space this had previously occupied. Six weeks later the optic disks were normal and the patient was returned to duty.

Commentary

Various diagnoses had been suggested, among which were tuberculous meningitis, intracranial tumour, and subdural or subarachnoid haemorrhage. On clinical grounds these were eventually reduced to haemorrhage or a tumour which might have been either in the right frontal region or in the posterior fossa, the subtentorial site being suggested particularly by the intensely choked optic disks. Ventriculography would in all probability have at once determined the location, but this was conveniently done by electro-encephalography, the great advantage of which, as Rendle Short and Miss Dunster have pointed out, is its relative simplicity and harmlessness—unlike ventriculography and aero-encephalography, which are not simple or altogether devoid of the risk of unpleasant consequences. As these writers also point out, it remains for the future to show how accurate localization by electro-encephalography will prove to be: but meanwhile it is important to record experiences of it as these are encountered. It might be anticipated that a meningeal haemorrhage (vide Rendle Short's case, previously referred to) and a subdural haematoma (case here recorded) would behave electro-encephalographically somewhat similarly because in each case the cerebral cortex is separated from the skull by a comparatively good conducting medium—namely, the haematoma. This was found to be the case by Jasper and his co-workers (1940), who point out, however, that, in contradistinction to such extracerebral collections of blood, an intracerebral haemorrhage may sometimes be detected and localized by the delta activity arising from surrounding grey matter damaged by the haemorrhage in the substance of the brain. If this is confirmed, electro-encephalography will be still more valuable in the investigation of cases of intracranial haemorrhage by providing some guide to subsequent surgical procedures.

One further feature of the case here recorded may be noted. Normal disks and normal vision are now present after a high degree of choking (approximately 5D) of both optic disks from the end of July until early in October, when the patient consented to operation. How long the retinae are capable of withstanding a high degree of choking of the nerve heads before showing signs of optic atrophy and visual impairment is an important problem still not completely decided, but among other factors the age of the patient is probably important. In this particular case the retinae of a man aged 20 were able to sustain a high degree of papilloedema for some nine to ten weeks without subsequent atrophy of the optic disks or any evidence of visual impairment.

Summary

The electro-encephalographic findings in a case of traumatic intracranial subdural haemorrhage are noted. These, together with those of the few cases hitherto described, constitute cumulative evidence of the value of electro-encephalography as an aid to the detection and location of traumatic intracranial haemorrhage.

The retinae of a man aged 20 were able to withstand high choking of the optic disks for some ten weeks without subsequent interference with function, vision returning to normal after operation and the papilloedema subsiding without signs of atrophy.

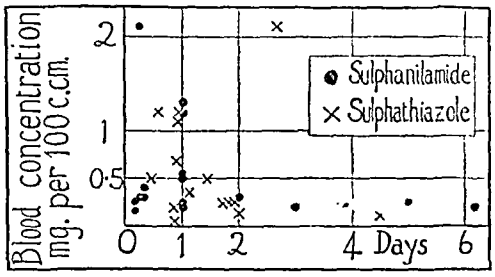
BLOOD CONCENTRATIONS FOLLOWING LOCAL APPLICATION OF SULPHONAMIDE COMPOUNDS TO WOUNDS

BY

FRANK HAWKING, D.M.

WITH A NOTE BY



J. E. PIERCY, F.R.C.S.Ed.

The insertion of sulphonamide compounds into wounds to prevent or reduce bacterial infection is a procedure that is now widely practised, and it will doubtless become more important in the future because of its promising results and the increasing number of wounds to be treated. The present paper describes the concentration of the compound which occurs in the blood following this procedure.

The observations have been made mostly with sulphanilamide and sulphathiazole. Each compound was applied as a powder sprinkled into the wound. In fresh wounds this was done at the time of the first operation, following débridement; the wounds were then closed by primary suture whenever possible, and compound fractures were put up in plaster. These procedures were performed by the surgical staffs of the New End Hospital and of the Hampstead General Hospital. The compounds were also inserted into a number of sinuses with chronic sepsis and into large ulcers associated with varicose veins of the leg. The powder was prepared in 5-gramme lots in small glass bottles with screw caps, such as are used for bacteriological specimens; these bottles can then be sterilized by dry heat or by any other method desired for the operating theatre. The estimations of the compounds in the blood were made by the method of Marshall and Litchfield (1938). Concentrations are expressed as mg. per 100 c.cm. of sulphanilamide or of sulphathiazole respectively.

The concentration of sulphanilamide found in the blood of these patients is shown in the table and the graph: the latter refers only to cases which received a single application of the compound. The figures are irregular, as might be expected from the diversity in size and conditions of the wounds, but the blood concentration

after twenty-four hours rarely exceeded 1.5 mg. per 100 c.cm., and usually it was only 0.5 mg. or less. After the first forty-eight hours the blood concentration (with one exception) was negligible.

Discussion

These concentrations are much lower than those found by Jensen, Johnsrud, and Nelson (1939). Those workers inserted 5 to 15 grammes of sulphanilamide into 41 cases of compound fracture and observed a maximal blood concentration of 6 to 14 mg. per 100 c.cm. at eighteen hours; after sixty hours the concentration was negligible. The difference in results is probably due to the difference in quantity and identity of the compound applied and to the nature of the wounds treated. Herrell and Brown (1940) inserted 1.6 grammes of sulphanilamide as a suspension three times daily into infected pleural or peritoneal cavities and observed blood concentrations as high as 2.5 or 3 mg. per 100 c.cm.; but when the compound was applied to other sites—e.g., fractures or ulcerations—the blood concentrations were minute. It may be concluded from these results that treatment by insertion of a sulphonamide compound into a wound can safely be reinforced by oral administration, and that if the bacteriostatic effect is desired at other sites in the body, outside the wound cavity, such reinforcement is desirable.

Table showing Blood Concentration of Sulphonamide Compounds following Local Application to Wounds

Nature of Wound	Dose (gm.)	Interval since Insertion (hours)	Concentration mg./100 c.cm. Free	Total
Sulphanilamide				
Sinus in buttock (first application) ..	2.5	6	0.3	
		24	0.2	
Ditto; continuous packing over long period	2.5 (every 2 days)	24	1.2	
" " "	2.5 (tablets)	24	0.55	
		48	0.28	
Two varicose ulcers, each 3 in. × 3 in. ..	2.5	4	0.25	
		8	0.4	
		24	0.5	
Raw area 6 in. × 3 in. from varicose ulcer	2.5	4	0.15	
		8	0.3	
		24	0.25	
Wound in buttock	5	6	2.0	2.0
		120	0.25	0.39
		148	0.2	0.2
Wound in thigh	5	24	1.3	2.5
		72	0.22	0.48
Sulphathiazole				
Sinus in buttock (same as above): continuous packing over long period ..	2.5 (every 2 days)	48	1.1	1.5
Compound fracture of radius and ulna ..	3.5	21	0.04	
Fracture-dislocation of knee	3	11	0.5	
Compound fracture of tibia and feet ..	4	23	1.2	
Laparotomy wound breaking open ..	3	27	0.35	
		46	0.25	
Wound in shoulder	2.5	22	1.1	1.9
Amputation of arm	5	35	0.49	1.3
Deep wound in brachialis muscle	2.5	14	1.2	1.2
Wound of laparotomy for tubo-ovarian abscess	2.5	64	2.1	2.0
		108	0.1	
Compound fracture of tibia and fibula ..	5	21	0.2	0.2
		45	0.24	0.24
Suprapatellar wound	5	21	0.68	0.68
		45	0.24	0.24
Carbuncle	3	48	0.12	0.12
Sulphapyridine				
Two varicose ulcers, each 2 in. × 1 in. .	2.5	6	0.15	
		24	0.1	
Two varicose ulcers, about 2½ in. × 1 in. ..	2.5	6	0.1	
		24	0.12	

Of the clinical effect of this treatment it may be said, briefly, that all the cases of fresh wounds and fractures progressed excellently, while the sinuses with chronic sepsis and the ulcers due to varicose veins appear to have improved. A more detailed account of the clinical aspect is given in a separate note on the application of sulphathiazole to wounds by Mr. Piercy.

Note on the Application of Sulphathiazole to Wounds

In the past four to five months all air-raid and street casualties with open wounds (the result of falling masonry and penetrating bomb fragments, and including tissues both lacerated and burned by incendiary bombs) have been treated after débridement and removal of foreign bodies by dusting approximately 5 grammes of sulphathiazole deeply into the lacerated tissues. These injuries include compound fractures and compound fracture-dislocations. In the latter cases the suture lines also have been dusted with sulphathiazole before the plaster is applied. If the loss of skin does not permit of suturing sterile vaselined gauze impregnated with the powder has been packed into the wound. The results have been highly satisfactory, the majority of the cases healing by first intention and the temperature falling within seven days—certainly a higher percentage than we found before this practice.

The following are two illustrative cases:

Case 1.—A young girl fell from a height on to the back of her hand, sustaining a compound fracture of the radius and ulna; both proximal fragments were forced into garden earth, which had displaced upwards, and replaced, approximately one and a half inches of the bone marrow. At operation the earth was curetted out and the medullary cavity was packed with sulphathiazole; this was followed by approximation of the fragments, suturing of muscles and skin, and application of a plaster cast. At the removal of the first plaster there were two small sinuses, which soon healed. Bony union is taking place.

Case 2.—A young man with a badly lacerated quadriceps muscle opening widely into the knee-joint was treated with sulphathiazole as above. A small rubber drainage tube, however, led down to the capsule of the joint. The skin was healed by the eighth day, but the small tube had disappeared, apparently into the tissues. Subsequently a search under gas failed to find it, and the wound was resutured. Following radiography, the wound was again explored six days later, and the tube was found actually in the knee-joint. In spite of all these manœuvres the wound healed perfectly, without any evidence of sepsis or sustained rise in temperature.

Summary

Patients with wounds, suppurating sinuses, and varicose ulcers were treated by the local insertion of sulphanilamide or sulphathiazole (up to 5 grammes). The concentration of sulphonamide compound in the blood after twenty-four hours was rarely above 1.5 mg. per 100 c.cm., and usually it was less than 0.5 mg. per 100 c.cm. Consequently it seems that this local treatment can safely be reinforced by oral administration of the compound, and that in many cases such reinforcement would be desirable.

Grateful acknowledgments are due to the superintendent of the New End Hospital, the Hampstead General Hospital, and the respective surgical staffs for permission and assistance in observing these patients; to Messrs. May and Baker and Burroughs Wellcome for supplying the compounds; and to Dr. A. T. Fuller and Miss M. Kuck for assistance with the chemical estimations.

PNEUMOCOCCAL SEPTICAEMIA WITH RECOVERY

BY

J. ELLIOT MURRAY, M.D., Ch.B.

AND

S. ORAM, M.B., B.S., M.R.C.P.

Excluding the transient bacteriaemia of lobar pneumonia very few instances have been recorded of pneumococcal septicaemia, proved by blood culture, in which a cure has been obtained as a result of giving sulphapyridine. The case to be described presents sufficient unusual features to make it worth publishing.

Case History

The patient, an Army officer aged 39, was wounded on May 20 1940, in Norway by flying bomb-splinters, and received a severe laceration of his left calf and a small wound below the left patella. No fracture was sustained. He was admitted to a Liverpool hospital, and the infrapatellar wound completely healed within six weeks. The calf wound was treated by débridement and plaster, and after four months the plaster was removed and replaced by elastoplast. Although this wound had not quite healed the officer was allowed to go home to the South of England as an ambulant patient on November 18. For the first five days of his leave he felt very well, but at midnight on November 23 he suddenly developed a rigor and much retching occurred. The following morning his temperature was 103° F. and a heavy cloud of albumin was present in the urine. A tentative diagnosis of acute pyelitis was made and appropriate measures were instituted. No dysuria was present. Early on the fourth day of the illness the patient noticed a slight sore throat, and this rapidly became worse. On November 28 he was admitted to our hospital.

On examination he was found to be nearly moribund, with a temperature of 106° F. A short time after admission a rigor occurred. His throat was almost uniformly injected, possibly slightly redder in the left peritonsillar region, but no membrane was present. There was a concomitant bilateral cervical adenitis. The calf wound was almost completely healed, but a little thick greenish pus was seen. No cellulitis was present and no crepitus was obtained. There was no tenderness over the kidneys or in the hypogastrium, and although his urine showed a heavy cloud of albumin and was strongly acid the guaiacol test was negative. The spleen was not palpable. The heart sounds were distant and tic-tac rhythm was present together with some degree of cardiac dilatation. The blood pressure was 108/76 mm. Hg. His other systems were normal.

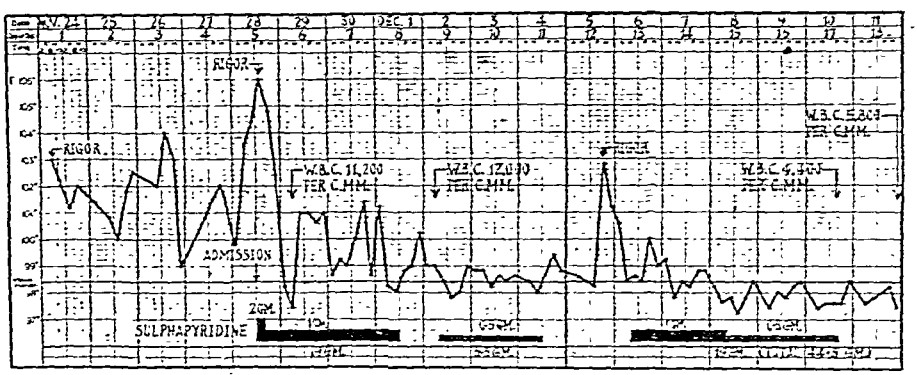
Four 0.5-gramme tablets of sulphapyridine (M & B 693) were given immediately, followed by two tablets four-hourly.

Pathological Investigations

"*Throat Swab.*—Pneumococci predominate. Non-haemolytic and other organisms present.

"*Direct Smear from Wound.*—Pneumococci predominate. On culture pneumococci and a Gram-negative bacillus, possibly *B. friedlanderi* were grown.

"*Blood Culture.*—Culture shows a pure growth of pneumococci.



"*Urine.*—Acid reaction, albumin + —, sugar *nil*, acetone *nil*. Deposit: one granular cast, one or two leucocytes and epithelial cells, and a few coliform organisms, not in excess.

"*W.B.C. Count.*—11,200 per c.mm.—polymorphs, 87.2%; lymphocytes, 11.6%; basophils, 0.4%; eosinophils, 0.8%.

"*Radiograph.*—The contour of the left ventricle is suggestive of a degree of dilatation. The lung fields are normal."

Progress

On the morning following the day of admission a small swelling about an inch in length and half an inch in width suddenly appeared in the long axis of the inner aspect of the right forearm. It was red, tender, warm, and indurated. Local heat was applied and by the next morning no trace of this swelling could be found, but another swelling had appeared between the lower border of the thyroid cartilage and the suprasternal notch. This was more diffuse and more tender than its precursor, and extended beneath the left sternomastoid muscle. The overlying skin was red and oedematous but not adherent. No fluctuation was obtained. This was an acute diffuse thyroiditis. Antiphlogistine was applied over the swelling, which became more brawny during the next few days and then gradually disappeared.

By December 1, as the temperature had fallen to normal and the patient had received 19 grammes of sulphapyridine, an attempt was made to stop the drug, but by the same evening the temperature had risen to 100.2° F. A W.B.C. count the following day showed a total of 12,000 per c.mm., so sulphapyridine, one tablet four-hourly, was restarted. Two days later a second attempt was made to stop the drug. The day after doing so, however, the temperature rose to 102.8° F. and a rigor occurred, so a reversion to the original dosage was made. This time the drug was continued until the temperature had remained normal for three days. In all 44.5 grammes of sulphapyridine was given, and by now a moderate leucopenia had resulted, the white cells numbering 4,400 per c.mm.; by the next day this figure had already risen to 5,800 per c.mm. The albuminuria gradually decreased, and was quite gone by December 7.

Commentary

The heavy albuminuria and pyrexia with rigors suggested pyelitis, but that diagnosis was contradicted by the absence of appropriate clinical signs and of pus or organisms in the urine. The albuminuria presumably resulted from the fever.

As the pus from the wound yielded pneumococci, as did the throat and blood stream, it was thought that the primary focus was the calf wound, although six months had elapsed since the wound occurred and no history of recent trauma was obtained. It was considered unlikely

that the inflamed throat was the origin of the infection because this lesion followed four days after the raised temperature. Unfortunately no smear from the wound was taken soon after the injury.

Presumably the transient swelling in the forearm and the thyroiditis were septicaemic manifestations. The appearance of the thyroid closely corresponded with the description given by Giordanengo (1938), who states that only 54 cases of acute non-suppurative thyroiditis have been recorded.

During the administration of sulphapyridine no precautions were taken regarding sulphur-containing foods or drugs and no cyanosis occurred—in fact, the patient felt extremely well after the first few days and no nausea was experienced at any time. Radley Smith (1940) has shown how completely unjustified is the fear of administering sulphur-containing compounds during sulphapyridine therapy. The only substance which it is necessary to restrict, at least for the first few days, is water. This is often overlooked. It is impossible to obtain the optimum concentration of 10 to 15 mg. of sulphapyridine per 100 c.cm. of blood if the patient is allowed fluids *ad lib*. It is surprising that in such a debilitated patient the white cells did not become more greatly reduced. Young (1937) has stated that especial care is necessary in such ill patients, and has shown how inadequate a safeguard are frequent blood counts, since preceding counts often give no indication of the imminence of complete and fatal agranulocytosis. As it was, the total amount received by our patient was very near 50 grammes, which is considered by Sutherland (1939) to be dangerous. The individual susceptibility of patients must vary very considerably.

In all the cases we can trace there has been a delay of several days, due to difficulties in diagnosis, before the administration of sulphapyridine has been started. Bonorino Udaondo and Pinedo (1940) waited five days, and Southwood and Magarey (1940) did not begin chemotherapy till the seventh day, and in each case a cure was obtained. In both of these cases, as in our own, the drug was stopped too soon and had to be repeated.

Summary

The interesting features of this case appear to be:

1. The isolation of pneumococci from a leg wound, the throat, and the blood stream, and the long latent period of six months from the original wound to the onset of septicaemia.

2. The transient nature of inflammatory swellings in the arm and neck, which subsided without surgical intervention.

3. The relatively large amount of sulphapyridine (44.5 grammes) necessary to maintain a normal temperature, and the absence of any ill effects.

4. The long delay of four days before starting chemotherapy and the rapid and complete recovery of the patient.

F. E. Norris (*Brit. J. Inebriety*, 1941, **38**, 112) states that the relation between alcoholism and crime is becoming an academic question and is now less important in the consideration of the causes of crime as a whole than formerly. Criminals in this country are not commonly addicted to alcohol and are not greatly concerned by its withdrawal after admission to prison. They rarely attribute their delinquency directly or indirectly to alcohol. In cases where there is a recognizable relation between alcoholism and crime the offences committed are only some types of sexual offences rather than the much commoner offences against property.

Clinical Memoranda

Amnioplastin as a Conjunctival Graft

This case is reported because we consider that amnioplastin has some advantages over mucous membrane grafts and possibly, too, over de Rötth's (1940) whole foetal membrane grafts, in that it is always available, is easily sterilized, and on account of its amorphous character lends itself admirably to conjunctival repair. Furthermore, it does not necessitate an additional wound at the graft source. It is suggested, therefore, that this might be a useful adjunct in the repair of civil and military eye wounds at the present time.

CASE RECORD

A quarry worker aged 54 sustained an injury to the strip region of his left lower lid by a fragment of stone in August, 1939.

When first seen, four months later, at the out-patient department of the Aberdeen Royal Infirmary he had a somewhat sessile mass on the middle of his lower eyelid conjunctiva measuring 7.5 mm. by 5.5 mm., and infiltrating the base of the lesion was a bead of dark pigment. Radiographs failed to reveal any foreign body, and no enlarged nodes were palpable.

It was decided, as a preliminary measure, to implant the area with radon seeds, giving 6,000 *r* at a distance of 0.5 cm. from the skin surface, and this was carried out on January 19, 1940. Biopsy taken at the time of implant showed the growth to be a malignant melanoma with an admixture of septic granulation tissue. Soon after treatment all the pigmentation disappeared, but at the end of five months, during which the patient was kept under close observation, a faint brown spot reappeared in the treated area and there was still some residual thickening of the centre of the eyelid. This was regarded with suspicion, and it was thought advisable to excise the lid. Actually no trace of malignancy was found in the tissue on microscopical examination following its removal, though metastases and secondary glands became evident before the end of the year.

On June 18, under evipan anaesthesia, the lower lid was excised medially as far as the lower punctum and inferiorly to beyond the lower fornix. Amnioplastin was used to replace the conjunctiva, being prepared and sterilized by boiling to obtain the maximum shrinkage before use, after the method suggested by Chao, Humphreys, and Penfield (1940). A flap of the membrane was sutured to the lower edge of the cut ocular conjunctiva and also to the skin at the lower edge of the wound, so as to make a deep fornix. The free end was then reflected upwards and sutured to the upper border of a pedicle flap from the left temple which was swung over to form the new lower lid. It will thus be seen that the lower lid was replaced and the space between the graft and the eyeball was lined by a double fold of amnioplastin.

During the next few days the only treatment carried out was the instillation of cod-liver oil drops into the eye and the covering of the whole wound area by saline soaks. Healing was satisfactory, and in just over three weeks the base of the pedicle was cut, the amnioplastin and graft having taken well.

When seen three months later some shrinkage of the artificial conjunctiva had taken place near the outer canthus, causing a symblepharon, which, however, has given no discomfort. The inner part of the fornix was of fair depth. No attempt had been made to prevent symblepharon during healing, as is commonly done, by passing a glass rod round the fornix.

TWO BRITISH PREPARATIONS FOR

LOCAL ANAESTHESIA

Introducing

FOR SURFACE ANAESTHESIA

'ANETHAINE' brand of butethanol is an extremely powerful surface anaesthetic. This substance, chemically allied to procaine, has hitherto only been produced abroad, but it is now manufactured by Glaxo Laboratories at Greenford.

A 1 per cent. solution of 'Anethaine' gives approximately the same effect as a 10 per cent. solution of cocaine. Therefore, although the absolute toxicity of 'Anethaine' is two or three times greater than that of cocaine, its toxicity in the dilute solutions actually used is much lower.

APPLICATIONS: Ophthalmology; oto-rhino-laryngology; urology. Anethaine produces effective surface anaesthesia for operative procedures on the eye, nose and throat, and for relief of painful conditions in accessible parts of the body covered with mucous membrane.

ANETHAINE

BRAND OF BUTETHANOL

Solution, 2 per cent. (coloured blue) in 25 cc. bottles; powder in 1 and 5 gm. bottles.

PRODUCTS OF THE GLAXO LABORATORIES

for INFILTRATION AND REGIONAL ANAESTHESIA

British preparations of procaine hydrochloride, and procaine hydrochloride with adrenaline, are now presented under the name

SEVICAINE BRAND

1 per cent. solution of procaine hydrochloride in boxes of 3×10 cc. ampoules; 2 per cent. in 15 cc. rubber-capped bottles; 2 per cent. with adrenaline (1 in 60,000) in boxes of 6 and 12×2 cc. ampoules and 15 cc. rubber-capped bottles.

GLAXO LABORATORIES LTD., GREENFORD, MIDDX. BYRon 3434

thought and practice in America. The whole volume is well supplied with references, there are many valuable illustrations, and the index is good. Search in various sections chosen at random has revealed that the essential practical nature of the earlier editions has been well maintained. A curious omission discovered by chance is the absence of any reference to eumydrin for congenital pyloric stenosis. One other criticism is that the section on nutritional requirements appears to be very complicated and hard to read, probably because too much material has been condensed into a relatively short space. In general, however, this can be welcomed as a first-rate contribution to medical literature.

ELEMENTARY EXPERIMENTAL PHYSIOLOGY

Experimental Physiology for Medical Students. By D. T. Harris, M.D., D.Sc., F.Inst.P., Professor of Physiology, London Hospital Medical College. Third edition. (Pp. 292; 248 illustrations and plate in colour. 15s.) London: J. and A. Churchill. 1941.

The third edition of this book, originally based on the intermediate medical course in physiology at University College, London, continues the valuable service rendered by previous editions. Any student who follows it through will have obtained a good introduction to the methods used in physiological inquiry, and it can be recommended to any teachers of the subject as a basis on which to build courses suitable for their own departments.

The book contains several new features, notably a rewriting of much of the chapters on the analysis of the respiratory gases and of the blood gases. On the whole these chapters have been much improved, but it is unfortunate that the Van Slyke manometric apparatus is only mentioned incidentally, and then in the form of an elaborate modification which has found little general application. It receives no mention in connection with blood gas analysis, though the Van Slyke volumetric apparatus is described. The sections dealing with tissue respiration, with special senses, and with pharmacological experiments have also received notable additions and improvements. Some new electrical apparatus will please those interested in wireless technique—for example, a neon tube stimulator, thyratron stimulator, L.F. oscillator, amplifiers, etc., but it may be doubted whether the information given about them would be of any use to the inexpert. The figures are clear and well selected, the only thing to cavil at being that the commercial illustrations of apparatus are taken from too narrow a field of makers. The printing and general get-up are all that we are accustomed to expect of Messrs. Churchill.

VERTEBRATE HISTOLOGY

The Microscopic Anatomy of Vertebrates. By James I. Kendall, Ph.D., D.Sc. Second edition. Thoroughly revised. (Pp. 342; 197 illustrations. 17s. 6d. net.) London: Henry Kimpton. 1940.

The second edition of *The Microscopic Anatomy of Vertebrates*, by Dr. James Kendall, is a revision with additional illustrations of the previous edition. The original purpose of the book was to provide a practical knowledge of the microscopic anatomy of vertebrates, founded on representative types of the various classes. The material which has been made use of has thus been derived from such types as the dogfish, Necturus, lizard, pigeon, rat, rabbit, cat, or dog. References have been made to other types, where necessary, and certain facts of comparative anatomy have been introduced, which add to the general interest of a purely structural description of the tissues. The systems and organs have been dealt with in an orderly manner, which facilitates reference, but, as sometimes happens, the strict adherence to plan has in some places led to much repetition. The introductory chapters will be especially valuable in assisting beginners, by means of stereodiagrams placed side by side with photomicrographs of the same tissue, to interpret the different appearances produced by variations in the planes of section. The author has not attempted to do more than give a general description of microscopic anatomy, and has accordingly relegated the more detailed study of certain structures, such as the brain, sense-organs, or endocrine glands, to special works in which these subjects are dealt with from the standpoint of human or comparative anatomy, in a much more exhaustive manner than is possible in a textbook limited to a general survey of the basic principles of microscopic anatomy. The author has, however, provided for this contingency by giving a valuable selection of references to the literature on the several systems, which should prove to be an assistance to further study of the particular organs and systems. There is an excellent concluding chapter on the technique of preparing sections, which contains the practical information indispensable for the laboratory worker.

The book may be highly commended as an introduction to the study of vertebrate histology and as an incentive to further study.

Notes on Books

Like many another medical man, Mr. ANDREW RUGG-GUNN has fallen under the spell of Egyptology. In his *Osiris and Odin: The Origin of Kingship* (H. K. Lewis and Co., Ltd., 8s. 6d. net) he shows himself as an avowed "diffusionist" of the Elliot Smith school. After reciting the myth and cult of Osiris he maintains that in his migration northward this god became the Odin of Scandinavia. This view necessitated dating the introduction of Odin worship by many centuries earlier than is ordinarily done, but the author makes out a good case for so doing. A specially interesting contribution to his thesis is the map showing that the route of this migration was used on a return journey by the traffic from Jutland of the "life-giving" amber to Apollo's island of Delos. But more than amber took this journey, for if Mr. Rugg-Gunn's view is correct, Osiris, transformed into Odin, must have come back again as Zeus, accompanied by other northern deities who were established on Olympus when the Achaeans from the north invaded the Mediterranean countries. This is a point, however, which he does not raise. Agriculture, kingship, religion, form the tripod on which the Osiris and Odin cults alike rest. Mr. Rugg-Gunn traces our present discontents to the depreciation of those values, and makes an impassioned appeal for their restoration. Not everyone will agree with all the views expressed in this interesting book, but no one will question the author's deep sincerity. Incidentally a number of rather striking suggestions are made, such as that the present position in Italy is a revival of dual kingship, which has never been long in abeyance in the history of that country that in the United States society appears to be reverting to the matriarchal system, and that much of our coronation symbolism is drawn from the rites of Osiris. Altogether a pleasantly stimulating book.

A copy of the *Collected Papers from the Middlesex Hospital*, published during 1939–40, has been received from the cancer and general research committee of the hospital, and can be consulted in the Library of the British Medical Association.

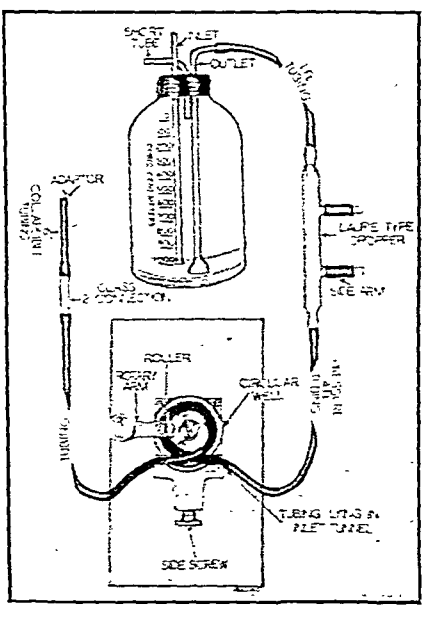
For the sixteenth edition of the popular *Black's Medical Dictionary*, by the late Dr. J. D. COMRIE, extensive revision has been made and new sections on the ductless glands and on the sulphonamides added. The special wartime supplement on air-raid casualties which was included in the previous edition has also been revised in the light of practical experience. The publishers are A. and C. Black, and the price is 20s.

Preparations and Appliances

USE OF THE ROTARY PUMP IN INTRAVENOUS THERAPY

Mr. G. M. ARNOTT, resident surgical officer, Children's Hospital, Birmingham, writes:

The technique described below has in my opinion proved to be superior to the more common methods of administering fluid intravenously. The fluid can be given at an accurate speed, from a slow drip to a continuous stream under pressure, and is introduced by siphonage, making elaborate containers unnecessary. These advantages are effected by the use of Riddell's rotary pump.



Mechanism of Pump.—The pump is constructed of metal and has an ingenious but simple mechanism. There is a "circular well," a section of which moves radially on turning the "side screw," either opening or closing the well. Within the well is the "roller," carried by the "rotary arm." By opening the well and manipulating the rotary arm the pump is easily charged with a turn of rubber tubing, the supply and delivery ends fitting in their appropriate tunnels in the wall. The tubing will lie with the wall of the well on its outer side and be compressed by the roller on its inner side. If the well is now closed, rotation of the arm will set the pump in action. A continuous wave of compression is exerted on the turn of tubing by the rotating roller, giving a positive pressure ahead and a negative pressure behind. When the rotary arm is in "neutral" the roller is opposite the centre of the movable section, and with the well closed the tubing is compressed and clipped off at this point. The lumen of the tube is re-established to any degree by turning the side screw and opening the well, providing an accurate drip-regulator.

Outfit.—The apparatus, which may be arranged as a portable unit, is assembled as follows (see diagram):

A wide-necked bottle, capacity 1,000 c.cm., containing the fluid to be administered, is fitted with a rubber bung, pierced by three lengths of glass tubing, two reaching to the bottom of the bottle and the third stopping short of the 1,000 c.cm. level. One long tube, the outflow, has its lower end shaped like an inverted thistle funnel, diameter 3/4 in., to act as a filter when covered with a few layers of sterile gauze. The second long tube is the inlet when taking blood or using filtered oxygen as an agitator. Pressure is equalized through the short tube, which is open in all procedures.

To the outflow are connected in series: (*a*) 1 ft. of rubber tubing. (*b*) A glass dropper of the Laurie type. The bulb should be 1 1/2 in. to 3/4 in. in diameter and about 6 in. long. If the column of fluid in the bulb tends to rise and obscure the point of the dripper the tubing above is clipped and a side arm on the bulb opened. When the required fluid level is reached the side arm is closed and the drip restarted by releasing the tubing. (*c*) 4 ft. of pressure tubing, outside diameter 9/32 in. This type and size of tubing must be used in the pump, which is threaded with this length. (*d*) a 2-in. glass connexion. (*e*) 4 in. of collapsible tubing. (*f*) An adaptor. All adaptors, cannulae, and needles should be of standard Record fitting, preferably with bayonet catches.

Venepuncture and Venesection.—Both in emergency work and in infusions lasting up to about six hours venepuncture is the procedure of choice if the veins are suitable; otherwise venesection must be performed. In either case an appropriate head of pressure is obtained by placing the container 2 to 3 ft. above the vein. The siphon is established with a clear fluid, an important point in performing venepuncture. If blood or plasma is to be given the bung is removed from the container and the filter immersed in saline, which is pumped through the tubing until all air is expelled and an even flow comes from the adaptor. The dropper meanwhile is held upright to obtain a suitable level of fluid in the bulb. When this has been completed the pump is stopped and the bung, if removed, is replaced in the container, care being taken not to shake the tubes and introduce air-locks. The container is placed in position. In venesection the adaptor is now attached to the cannula and the flow started by slowly rotating the arm of the pump two or three times, finally stopping in neutral. The drip will start and its speed be regulated by relaxing the side screw. In venepuncture the needle is attached to the adaptor while the siphon is being established and the bung fitted in the container as before. The skin over the chosen vein is prepared and, steadying the vein between the second and third fingers of one hand, the needle, held in the other hand, is introduced under the skin.

The rotary arm is reversed a few turns and the collapsible tubing will deflate. The operator watches the glass connexion, and when the vein is entered the reflux of blood will at once appear in the window. The needle is strapped in this position and the infusion started as before. Temporary distension of the vein will facilitate the operation, and in difficult cases a very small skin incision may prove helpful. A No. 16 S.W.G. needle with a short sharp bevel is used.

Advantages of the Method.—The advantages of having the pump in the circuit can now be considered. All drips are prone to slowing or stopping, and if a rapid inspection reveals a correct head of pressure, no obstruction in the filter or tubing, and no external pressure on the vein, the hold-up is in the cannula, the most frequent site. The difficulty is overcome by closing the well and pumping through a few cubic centimetres, which will clear the cannula, and the drip can then be restarted. During a drip infusion a few turns of the pump hourly will give an even flow. In slow drips the accuracy of a volume control can be maintained only by keeping the inlet clear. With the one apparatus fluid can be given at any desired speed, and the rate of flow can be accurately maintained. Plasma is now being more widely used, and the pump simplifies this type of therapy.

Taking Blood.—Finally, the outfit provides a simple method of taking blood and renders this operation possible under most conditions. The technique is the same as that described for venepuncture, the dropper being excluded and the pumping reversed. The citrate is pumped into the container through the long straight tube, the vein is entered, and the blood is withdrawn in an even flow.

"Varistab": Corrigendum

By a slip of the pen the name of Messrs. Boots's new product "varistab" was misspelt in our issue of March 15 (p. 406).

BRITISH MEDICAL JOURNAL
LONDON
SATURDAY APRIL 5 1941

DISTRIBUTION OF AIR-RAID CASUALTIES

Recent correspondence in the *Journal* has drawn attention to a problem that has been exercising the minds of those responsible for the treatment of air-raid casualties in hospitals—namely, the delay in the treatment that occasionally occurs owing to the fact that one hospital is overloaded with work whilst another closely adjacent remains empty and idle. That this is not in the best interests of either the injured or those who have to treat them will be disputed by no one. It is not, however, clear how far this experience is general, nor is it easy to determine the causes of this inequality of distribution or, having determined them, to find a remedy that can be applied easily and quickly. It is one thing to draft a perfect scheme on paper and quite another to follow out in the actual conditions of a raid the details that appear so clear and simple on a cool page of print. The ambulances that arrive at an incident have to work in darkness and danger and in the expectation that their journey to one or more hospitals may be blocked as a result of bombing. Once, therefore, a clear path has been found leading to one particular hospital, it is only natural that subsequent journeys should be made along the same path unless orders are given to move off in other directions. Again, the pride of service which is characteristic of the voluntary hospitals of this country makes the hospital staff eager to take in more and still more cases, and reluctant to admit that its capacity is becoming overstrained. As a well-informed correspondent points out (p. 526), the ideal system for surgeon, physician, and patient would be for all the casualty services to work under the same direction as the hospital service. Control in any given district should have absolute authority during a raid to direct the activities of the varying components of the casualty services. Control should be the central co-ordinating nervous mechanism, receiving messages from the outside and, after quick use of its association fibres, issuing clear instructions for action. To what extent has Control this power, and to what extent is it inhibited from using it? How far is conflicting authority responsible for lack of co-ordination between the casualty services and the hospital? These questions should be asked and be answered, for there can be no doubt that the time that elapses between the sustaining of the severe injury and its treatment is one of the most important factors in determining recovery. Within six to eight hours, as our correspondent points out, bacteria in a wound can be effectively dealt with by the customary surgical toilet. We would not be thought to detract from the admirable and heroic work that has been done in rescuing and treating those who have been injured in circumstances that are without precedent in our history, nor would we suggest that the bad results of delayed treatment are on anything but a small scale. But apart from the human aspect, the quicker and more efficient treatment of, say, 10 casualties in every 100, and the possible saving of one additional life in a hundred, is something that everyone concerned in the casualty services must aim at and achieve, by tightening up the system that exists until it is as nearly perfect as we can make it. The principles upon which the taking in of stretcher cases is based and their bearing upon ambulance arrangements are being carefully studied by the Ministry of Health, and will no doubt be embodied in future instructions. The distribution of casualties from major incidents should then be carried out in a more satisfactory way.

Until a complete co-ordination of casualty services does exist, the hospitals must themselves take steps to ensure that no casualty receives treatment too late because of faulty organization or because of reluctance to admit that it can no longer deal with additional cases with the existing staff and equipment. The officer in charge of a hospital during a raid should make every effort to anticipate the moment when the burden of work will become excessive, and should send out well in advance of that moment a call for the help of a relief surgical team. It is obviously not possible for him to turn away casualties once they arrive in the hospital, but it is unfair to both the hospital staff and the patients to hesitate to ask for assistance. If, owing to faulty organization, the casualties are all sent to one hospital while a near-by hospital remains empty, then the only thing to do is to ask the latter to supply an additional team. There is no virtue in delaying to seek for such help, nor, we feel sure, will there be any lack of response. The visiting team, however, cannot be expected to give its services willingly or efficiently unless the fullest preparations have been made for receiving it, and it is the responsibility of officers in charge of casualty hospitals to see that preparations are made down to the last detail, with a clear conception on the part of everyone of their duties in assisting and informing the visiting team of all the routine matters of their own hospital with which they are so familiar. Many hospitals, of course, have well-devised emergency machinery smoothly running for this purpose. It remains now to see that every hospital reaches the same pitch of excellence. Before the full operating capacity of a hospital has been reached, for ambulances are still on their way, the moment comes for what has been graphically termed "switching," in order to divert the further flow of casualties to other hospitals. As the mechanism for switching still has flaws in it, there is all the stronger reason for planning the internal arrangements of the hospital with the care and thoroughness which the surgeon shows in his operative technique. This and many other points are described in the article at page 526.

There is one other aspect of the treatment of air-raid casualties to which brief reference may be made, and that is the provision of an alternative hospital service when bombing is so intense as to put out of action a large number of hospitals in the centre of a big city. In such circumstances it is obvious that use must be made of hospitals at the periphery of the town or in the country beyond it, and it will remain with Control to give the signal to divert all casualties to the second

r even the third hospital line of defence. For xample, a factory district, railway centre, or dock rea may be severely attacked, and it is not uncommon or one or more of the chief hospitals of a city to be ituated in these areas and involved in the attack. If he damage is so great that the hospitals can no longer arry on, then the next hospital line of defence must ome into action. Even if work is still possible at he bombed hospital in a dangerous area, conditions nay be such that it is impossible or even imprudent to onvey into it casualties from less dangerous areas of he city. Apart from the risks to the patients of such course, there is also the risk to the personnel of the asualty services. In any event it would seem desirable for hospitals situated in dock or industrial areas o receive only casualties resulting from incidents in hose areas, and not from the less vulnerable parts of he city, casualties in which should be moved to the eripheral hospitals. If all the hospitals at the periphery are themselves bombed, then the third line of defence, of auxiliary hospitals and buildings selected in advance as reserves, will have to be used, or provision may have to be made for the erection of huts or tents to serve as emergency accommodation. It is important that the working of the alternative hospital scheme or schemes should be familiar to main Control, Sub-Control, depots, aid posts, and ambulance officers, drivers, and attendants. Hospitals which have been bombed may nevertheless still have much of their essential equipment untouched, and some time ago instructions were issued that plans for its removal should be prepared. Transport difficulties in such circumstances can easily be visualized, and hospital authorities have been asked to consider in advance the minimum essential equipment and stores to be removed immediately if the hospital is to carry on in improvised buildings; a second list of less essential equipment should be ready, so that this can be moved later when transport facilities have improved. Many hospitals in the country already have these details worked out to the last safety-pin.

REHABILITATION OF THE INJURED

In the years preceding the war much attention was being given to the problems concerned in the restoration to working capacity of persons injured by accident. This was in part due to a growing appreciation of the economic wastage associated with dilatory and inefficient treatment of fractures, for in Great Britain, on a conservative estimate, some 200,000 fractures were being treated each year in peacetime. A comprehensive report by a special committee of the British Medical Association in 1935 was followed by the appointment of an Interdepartmental Committee of the Home Office and Ministry of Health, which announced its findings in interim (1937) and final reports (1939). There was unanimous agreement on the following principles: segregation of patients with fractures, continuity of treatment from the time of the fracture to the final stage of rehabilitation or reconditioning, and unity of control throughout the whole period of treatment. The Interdepartmental Committee in its final report stated that special "reconditioning" centres would be necessary for a minority of patients treated in organized fracture departments, and various schemes were suggested. It is generally agreed that the majority of patients with fractures—children, housewives, and sedentary workers—require no special rehabilitation other than that provided by the physiotherapeutic department of a hospital—for example, heat, massage, active exercises both individually and in classes, and, in certain circumstances, electrotherapy.

It cannot be emphasized too strongly that the process of preserving and restoring function (that is, rehabilitation) begins with the initial treatment of the fracture. On another page Mr. E. A. Nicoll rightly makes this point, and indicates in a highly informative article many useful ways of preserving maximum function during the period of immobilization until the fracture has united. There is, however, a small proportion of patients, particularly those suffering from industrial injuries, for whom the gap between the stresses of such remedial activities as a hospital massage department can provide and the stresses of full heavy work should be bridged by a final period of reconditioning treatment. The aim is to subject the patient through graduated work to the full stresses of his original occupation while under constant medical supervision. This constitutes the argument for the creation of rehabilitation centres such as the Midland Counties Rehabilitation Centre for Miners at Berry Hill Hall, the work of which is so clearly described by Mr. Nicoll. As he says, rehabilitation is not to be confused with vocational training, which is the quite different and numerically smaller problem of training in new work a man who is permanently incapacitated from following any work in his former trade. The results obtained at those highly specialized centres, each of which deals only with the injuries of a particular trade—for example, Berry Hill Hall (miners), L.M.S. Railway Hospital at Crewe (railwaymen), Albert Dock Hospital, London (sailors)—and each of which is run by a surgeon and team familiar with every kind of work in that trade, appear to provide very strong support indeed for those who urge the provision of such centres on a larger scale. It is still a problem how best to organize these centres. Should they be planned on a regional basis and each centre be available to serve all trades? Or should each large industry have its own centre or centres? The latter method is the only one so far adequately tested, and its success appears to be proven.

Many surgeons experienced in industrial injuries feel that rehabilitation is best effected through the medium of "light" work. There is no doubt that in certain circumstances this is an admirable method, and it has been employed with the happiest results for many years by Dr. O'Neill Sherman of the Carnegie Illinois Steel Trust. He is able to insist, as soon as he considers a man fit for any form of work, that suitable work is provided and that the man remains under his or his team's observation. Somewhat similar facilities are provided by a few industries in this country, but, as Mr. Nicoll points out, "light work if it is to be of any remedial value must be selected, supervised, and graduated by the surgeon, just the same as any other form of occupational therapy. In actual practice, light work usually terminates the surgeon's connexion with the case." Moreover, the ability of an injured work-

man to do "light work" provides more often than not an excuse for depriving him of a substantial amount of compensation without the provision of suitable employment. As the Workmen's Compensation Act stands at the moment it is often difficult to prevent the development of an anxiety neurosis, with resulting persistent disability for the injured workman. It is natural that a man with family responsibilities and dependent for his living on his own manual efforts should be apprehensive about his future capacity to earn an adequate living, and more comprehensive information on this problem would be welcomed from established rehabilitation centres. It is quite certain that malingerers and deliberate seekers after exaggerated financial compensation form a very small proportion of injured workmen. It is surely not outside the scope of legal ingenuity to alter the Workmen's Compensation Act so that anxiety of the type alluded to above should not be added to the physical difficulties of rehabilitation. No doubt appropriate suggestions will be made by the Royal Commission on Workmen's Compensation to which the subject was referred, and these, it is hoped, will ensure that the workman is able to take a more rational view of his injury.

Who should decide when the man is fit to return to work? It seems unfair that this decision should be left to one surgeon, however expert he may be. The present system appears more just to the workman, though the abolition of the undignified wrangling between the medical and legal professions in open court would be welcome. Would it not perhaps be better to arrange for an efficient medical committee to represent all interests, whose decision would be accepted by employer and employee as final? It is clear that rehabilitation centres on the present model have justified their establishment, and it is to be hoped that employers and workers, and their respective organizations, will continue united and co-operative efforts to prevent wastage of man-power and money which could well be used for other purposes.

MEDICAL USES OF RADIUM

The Medical Research Council's series of reports on the medical uses of radium has been interrupted by the war, and the majority of the radium centres have been unable to compile their usual statistical summaries of the results of treatment. Experimental work, however, is continuing, and reports of this have recently been summarized by the Joint Radiology Committee of the Medical Research Council and the British Empire Cancer Campaign.[1] At the Imperial College of Science and Technology the bombardment of a spherical shell of uranium oxide by neutrons from a radium-beryllium source at the centre of the sphere produced secondary neutrons in excess of the number of primary neutrons captured from the source. An attempt is now being made to start a chain reaction; by using these secondary neutrons it is hoped to get further neutrons by fission in excess of the number lost in the process. St. Bartholomew's Hospital is producing radio-active sulphur for biological investigations. Evacuation of the pre-clinical students to Cambridge has meant that the Cavendish Laboratory cyclotron could be used in this work, and the difficulty of detecting the very soft beta radiation of radio-active sulphur has been overcome. A knowledge of the metabolism of sulphur in the skin is likely to throw fresh light on the skin reactions to radiation. Thus the report from the Mount Vernon Hospital shows that soft x rays (117 kV) have a much greater effect than gamma rays on the tails of mice when equal physical doses are administered under identical conditions. The explanation may be that the photo-electric emission of sulphur produced by the soft x rays is six times greater than that produced by gamma rays. Both the Royal Cancer Hospital and the Radium Beam Therapy Research Centre have continued their work on the spatial distribution of radiation within the body. By the contour projector the dose at any point from any number of converging beams can be estimated, and the volume of tissue which is raised to any given dosage level can be defined. Taking the co-ordinates of any point and computing the dose from previously prepared charts is a more laborious method, but it has contributed materially to the improvement of the 10-gramme radium unit technique. The Radium Beam Therapy Research Centre has also made small condenser chambers of a mixture of bakelite and graphite, with a small addition of titanium, which are independent of wave-length over a wide range. As the chambers are easily made several hundreds can be used simultaneously in a Presdwood phantom for determining isodose charts.

The Strangeways Laboratory has shown that the effects of radiation can be quantitatively estimated by means of mitotic and degenerate cell counts. To obtain the best results when divided doses are used the second radiation should be given when the effects of the first exposure are wearing off. With the material used, the optimum spacing after an initial dose of 82 r was eighty minutes, but with an initial dose of 268 r the optimum spacing was found to be ten days. Thus the duration of the biological change would seem to be proportional to a very high power of the dose, a result which leads to interesting speculations. For example, as the lethal effect of radiation is always represented by a sigmoid curve, it has been difficult to imagine what happens to the few cancer cells which necessarily survive, even in a "cured" case, no matter how big the dose. If, however, the above proportions hold for large doses the effects of a dose of several thousand r may take years to wear off. It has been found by the same quantitative methods that gamma rays ($\lambda_{eff.} = 0.014$) are only half as effective on tissue cultures of chick fibroblasts as x rays ($\lambda_{eff.} = 0.107$, 0.150, and 0.363 A.U.), no difference between the three wave-lengths of the x rays being detected. Linking these results with similar studies on neutrons, workers have found that for ion densities above about 5×10^4 per cm. the biological action is independent of ion density, and that below this value it diminishes rapidly as the ion density decreases. Where, however, it is the outcome of a single successful ionization—for example, the lethal action on bacteria—it increases with increasing ion density. The same kind of explanation is put forward by the Edinburgh Institute of Animal Genetics for the fact that the production of gene mutations in the spermatozoa of *Drosophila* is independent of both the intensity and the fractionation of the dose of radiation. A gene mutation, like the bactericidal effect, is the result of a single successful ionization, and the total hereditary effect is thus directly proportional to the total dose received during the life of the cell. The relation between the life of a cell and that of the individual is not well known, but the results are obviously of importance to all whose work exposes them to radiation. The frequency of structural changes in chromosomes also depends only upon the total dose received, as no reunions of the broken pieces take place in the spermatozoon before fertilization; but as at least

[1] *Brit. J. Radiol.*, 1941, 14, 1.

two chromosomes must be broken for a structural change to occur the effect is proportional to about the 1.5 power of the dose, approaching the square of the latter with very small doses. In ordinary cells, where there is no block to the fusion process like that existing in spermatozoa, some restitution of broken chromosomes will occur, so that division of the dose over a period of time will result in fewer structural changes. The maximum chromosomal changes will thus be obtained by concentrating the dose into a short period of time.

EFFECTS OF SEVERE CALCIUM DEFICIENCY

The general effects on the growing organism of deprivation of calcium have been known for some time, but the recent studies of Kleiber, Boelter, and Greenberg[1] have brought out many new and interesting facts. Young rats were given a diet containing only 9 mg. of calcium per 100 grammes of food but adequate in all other respects. The caloric value of this diet was about 5 calories per gramme, and it would supply a child of 5 years, consuming 1,500 calories, with only 27 mg. of calcium daily, or little more than one-fortieth of the normal allowance. The first noticeable effect of the deficient diet was on the growth rate, largely as a result of decreased appetite but also because of decreased efficiency in the utilization of food. The calcium-deficient animals showed no other outstanding symptoms for the first seven to ten weeks. Then a decreased sensitivity and reactivity could be noticed. After two months (corresponding to some five years in the life of a man) any or all of the more drastic symptoms made their appearance. These included prostration, paralysis of the hind legs, black faeces, and haemorrhages from the anus and from the toe-nail bed. There was also polyuria. The paralytic foot-drop of one or both hind legs was probably a secondary effect of haemorrhages in the central nervous system. Immediately after the onset of paralysis the animals were extremely sensitive to touch, but within twenty-four hours the surface of the body lost sensitivity. Prostration and paralysis could be induced much earlier by means of mild, short galvanic shocks. It is striking to note that in not a single instance did tetany appear spontaneously as a result of this uncomplicated calcium deficiency, nor could it be provoked by electric or sound stimuli. Yet the serum calcium level of the deficient animals was generally between 4 and 6 mg. per 100 ml., a concentration which is supposed to be responsible for "low calcium" tetany in animals after parathyroidectomy. The findings of Greenberg and his associates certainly support the view that besides calcium deficiency other factors are concerned in the production of tetany. In magnesium deficiency in rats the blood calcium level remains normal, yet the animals are hyperexcitable and any startling noise throws them into tetanic convulsions.[2 3] A large percentage of calcium-deficient animals succumbed shortly after spontaneous or induced paralysis. Haemorrhages, which may occur in nearly every organ of the body, were the conspicuous feature of post-mortem examination, and were seen in the lungs, brain, bladder, gastro-intestinal walls (especially in the duodenum), nail matrix, and peritoneal cavity. Massive haemorrhagic areas were frequently found in the gluteal muscles. In addition to these macroscopic findings, histological examination revealed haemorrhagic areas in the cerebrum, medulla, brain stem, about the choroid plexus of the third ventricle, in the lower right temporal pole of the brain, and, only occasionally, in the spinal cord. Boelter and Greenberg believe that the haemorrhages were due to alterations caused by the deficiency in the blood-vessel walls. Needless to say, the skeleton was very poorly calcified: the skull hardly at all, and paper-thin. Some animals developed unilateral cataracts. With the exception of calcium blood constituents were normal, and it is noteworthy that serum phosphatase was unchanged. (In milder forms of calcium deficiency the bony frame is chiefly affected, but in severe depletion interference with the extraskeletal functions of the element apparently comes to the fore.) A change of diet to normal was followed by immediate resumption of growth and gradual recovery, though in some cases the loss of use of one of the limbs remained permanent and the animal dragged its leg along as in man after hemiplegia. Injection of calcium salts was of no help at all for the reason that it invariably caused death within twenty-four hours. Necropsy showed rupture of the abnormally thin (right ?) ventricle of the heart in a longitudinal line from the base to the apex.

URINARY ANTISEPSIS

Although the new urinary antiseptics have made it possible to control almost every case of urinary infection not due to gross obstruction or accompanied by severe renal damage, there is still some misconception of how these drugs should be used. It is imperative in the first place to identify the micro-organisms responsible. Infection by *Bact. coli* and other closely related organisms will usually respond with equal readiness to treatment with either mandelic acid or sulphanilamide. In *Proteus* infections mandelic acid is useless, because no amount of ammonium chloride will render the urine acid enough for this drug to act: *Proteus* breaks down urea to form ammonia, and if ammonium chloride is pushed in the hope of acidifying the urine the effect on the patient may be serious, while on the urine it is *nil*. This infection fortunately responds well to sulphanilamide, which acts even better in an alkaline than an acid urine. This indication is reversed for infections with *Streptococcus faecalis*, this organism being unaffected by sulphanilamide but amenable to treatment with mandelic acid. In mixed infections it may be necessary to use these two methods consecutively, first eradicating one micro-organism by the appropriate treatment, and then attacking the other. This has been the position since the introduction of sulphanilamide, but it has been both complicated and improved by the advent of sulphathiazole, a careful study of which has now been made by H. F. Helmholz[4] of the Mayo Clinic. This is the latest of a long series of investigations by which Helmholz has given precision and certainty to our knowledge of urinary antiseptic action. The method he has adopted is to obtain urine from patients taking the drug, estimate the drug concentration in it, add a known number of bacteria, and determine by quantitative culture after incubation whether they have multiplied (and if so to what extent) or diminished in numbers. It is perfectly legitimate to deduce from such experiments what will happen in the urinary tract itself. His experiments with sulphathiazole include over 2,000 such observations, using many strains of each species of bacterium and urine adjusted to three different reactions. As usual there is a good deal of strain variation in resis-

[4] *Proc. Mayo Clinic*, 1941, 16, 651

tance, some strains of *Bact. coli*, for example, being killed by quite low concentrations, such as 25 mg. per 100 c.cm., while others require much more. The effect of *p*H on antiseptic action corresponds to that for sulphanilamide: *p*H 7.5 gives the best effect, and higher concentrations of the drug are necessary to achieve it at *p*H 6.5 or 5.5. The order of bacterial susceptibility to sulphathiazole in ascending order is *Ps. pyocyanea, Streptococcus faecalis, Bact. coli, Bact. aerogenes, Proteus,* and *Staphylococcus aureus*. The fact that staphylococcal infection is the most easily controlled of all is perhaps clearer evidence of the alleged effect of sulphathiazole on this organism than has been obtainable in other fields of therapeutics. It certainly represents the greatest advantage of this drug over others as a urinary antiseptic, for staphylococcal infections of the urinary tract do not respond with the same certainty as others either to mandelic acid or to sulphanilamide. Sulphathiazole has thus filled the last important gap, and these three drugs intelligently used should furnish a complete armamentarium. The increasing complexity of efficient treatment and the uses of laboratory control are illustrated by a peculiar feature in the behaviour of *Streptococcus faecalis*. This organism, unlike all others, is more readily killed by sulphathiazole in an acid than in an alkaline urine: the effect is best at *p*H 5.5. Fortunately the concentration of sulphonamide compounds attained in the urine by only moderate dosage is so high that such refinements as the accurate control of *p*H are superfluous except in the most resistant cases.

WHOOPING-COUGH PROPHYLAXIS

This "plague of the nursery and school" attacked 53,065 children in 1940 and 329 died from it. Since Gardner and others awakened British bacteriologists to the importance of the smooth haemolytic virulent Phase I of the bacillus of whooping-cough the chief problem has been to discover and perfect a method of consistently making a sound prophylactic vaccine. Some years ago this *Journal*[1] pleaded that the vaccine producer should be in a position to guarantee antigenic efficiency when he hands over a vaccine to the doctor. With growing interest paediatricians have watched the accumulation of figures showing that highly protective vaccines have at times been made and used. Kendrick and others[2] in Grand Rapids, U.S.A., recorded a 15.1% attack rate among 2,397 carefully watched unvaccinated controls, contrasted with a 2.3% attack rate among 1,815 inoculated children. Sauer[3] in Evanston observed 286 infections among 1,730 unimmunized children, while only 32 occurred among 2,453 of the vaccinated. McCullough[4] kept under observation ninety-seven inoculated children; of these, twenty-three were in intimate contact—for example, by kissing or drinking from the same cup—with children suffering from pertussis. None of the twenty-three developed the disease. Laboratory experiments clearly indicate that the way is open for making and testing a potent vaccine. J. C. Cruickshank,[5] in 1937, by alcohol precipitation and acetone extraction of a tryptic digest of *H. pertussis*, made a fraction that protected 90% of mice against a dose of bacilli which killed twenty-nine or thirty unprotected mice. Lawson[6] sprayed his living culture with a curved needle on top of the larynx of mice and killed 93%, whereas 93% of mice given vaccine made from smooth virulent strains withstood the same dose without harm. Lawson by his carefully controlled work may have rendered as great a service to the producer of pertussis vaccine as Grinnell[7] did to the typhoid vaccine maker when he showed in 1932 that many commercial typhoid vaccines made with unsuitable cultures did not protect mice. Lawson similarly tested samples of five commercial whooping-cough vaccines and found that two gave high protection to mice tested later with virulent culture, while three vaccines were inefficient. One of these was made by destruction of intact cells and one was said to contain detoxified toxin. We may now be confident that children can be protected by a properly made vaccine proved before release to be efficient, preferably by animal test, for Sauer[3] holds that assay by agglutination and complement fixation is insufficient. A number of weekly injections—from four to eight according to different workers—are necessary, and the number of bacilli injected must be large—about 80 to 120 thousand million. Reactions do not appear to be unduly irksome. Hopes have at times been raised that vaccine given early may shorten or modify the attack. Most workers, however, are of opinion that vaccine is useless after the spasmodic cough is well established, and there does not seem to be convincing evidence that any vaccine proved protective by animal test has any effect even in the early stages—nor on general immunological principles is this probable.

HONORARY PHYSICIANS TO THE KING

The following have been appointed Honorary Physicians to the King for a period of three years: Sir Henry Bashford, Chief Medical Officer, General Post Office; Sir Weldon Dalrymple-Champneys, Bt., Deputy Chief Medical Officer, Ministry of Health; Dr. John Moorcroft McCloy, Chief Medical Officer, Ministry of Home Affairs, Northern Ireland; Prof. W. W. C. Topley, F.R.S., Head of the Emergency Public Health Laboratory Service; Dr. R. Veitch Clark, Medical Officer of Health, Manchester; Dr. William George Clark, Medical Officer of Health, Edinburgh; and Dr. James Ferguson, Medical Officer of Health, Surrey County Council.

The Annual Convention of the Canadian Medical Association will be held this year in June at Winnipeg, under the presidency of Dr. Gordon S. Fahrni, lecturer in surgery in the medical faculty of the University of Manitoba and surgeon to the Winnipeg General Hospital. Those who crossed the Atlantic for the combined Annual Meeting of the B.M.A. and the C.M.A. at Winnipeg in 1930 have happy recollections of Dr. Fahrni, and know him as a keen supporter of the ties between us and the Canadian profession.

This year's Annual Session of the American Medical Association will be held at Cleveland, Ohio, from June 2 to June 6. The A.M.A.'s centenary occurs in 1947.

The President of the Board of Education has appointed Dr. J. E. A. Underwood to be Senior Medical Officer to the Board in succession to Dr. J. A. Glover, who reaches the age of retirement on April 10.

LONDON UNDER AIR BOMBARDMENT: SOME MEDICAL ASPECTS

BY

V. ZACHARY COPE, M.D., M.S., F.R.C.S.

[In the introduction to a lecture delivered to the North of gland Branch of the B.M.A. on March 6 Mr. Cope described : aerial bombardment of London, which started last Septem- r, and mentioned first of all some of its indirect effects upon : health of the community. The factors concerned were the iurbance of routine, shortened sleeping-time, poor ventila- n at some of the places in which refuge was sought, and erference with essential services, especially water supplies ing to broken mains. Incidentally he expressed surprise at greater use was not made of rain-water collected in tubs tanks from roofs, which would, of course, be less easily erfered with by enemy action. He also pointed out how nspicuously the enemy had failed in one of his evident jectives—that of interrupting transport services. One iking proof of this was that although some inconvenience is caused by road diversions and occasionally by a tem- irary and local dislocation on the railway, yet every morning iring the bombardment the milk supply came punctually to e door of every citizen.]

Effect of Shelter Life upon Health

he health of many Londoners during the period of severe id prolonged attack from the air was affected by their ay for many hours at a time in protective shelters. It id been anticipated that shelters would be necessary, and iany, though not enough, had been provided, but it was ot foreseen that the continuous nature of the nocturnal ttack would necessitate the provision of sleeping accom- iodation. In these places, for some weeks before bunks ould be provided, people slept on improvised beds and in eck-chairs. One surprising complication was the onset i a number of cases of thrombosis of the deep veins of the g and consequent oedema of the ankle and foot, due to ie fact that a person reclining in such a chair is apt to ave his legs press unduly upon the lower transverse bar. 'he thrombosis is brought about by the continuous ressure with relaxed muscles. Dr. Keith Simpson (1940) as pointed out a more serious sequel in the form of pul- nonary embolism. The number of cases of sudden death lue to this cause reported in the various London districts n September and October, 1940, was 24, as compared with nly 4 in the corresponding months of the previous year. These cases of pulmonary embolism have disappeared ince bunks were provided, and it is reasonable to conclude hat there was a direct association between the two facts. t is possible that a further consideration of the mechanism of the production of thrombosis in such cases may furnish aluable information concerning the occurrence of post- operative thrombosis and embolism.

Another surgical complication directly attributable to he prolonged stay in shelters was the great increase in cases of retention of urine in old men. Cold and damp may have been contributory, but the main factor must have been the limited conveniences at first provided: opportunity could not be found to pass urine until the bladder was over-distended, and thereafter retention en- sued. Such cases will no doubt occur less frequently now that the shelters are better equipped.

A method of prophylaxis which, we are informed, may be introduced into the shelters can be properly commented upon by a surgeon—namely, the provision that has been made for the wearing of masks to prevent the spread of droplet infection. We are told that half a million masks are ready to be distributed as and when required. Surgeons have long acted upon the view that infection can easily be transferred by means of the breath, and the wearing of masks is a routine in the operating theatre. The human nasal and pharyngeal mucosa is in some cases as susceptible to infection as an open wound, and I have often been surprised that physicians have not strongly preached, and by force of example demonstrated, that contagion of the common influenzal cold could be pre- vented by the wearing of an efficient mask. If in the shelter, why not in the work-room or office? Making the reasonable assumption that in Great Britain every year one million people lose one day from work as the result of a cold, the time lost from this cause annually would equal nearly 3,000 work-years. Would it not be worth attempting to reduce this time by mask prophylaxis?

The direct mental effects of the bombardment con- founded the prophets. The predicted panic and mass hysteria did not occur, the plain fact of the matter being that the average British citizen, whether soldier or civilian, is brave and resolute, and when faced with danger pre- serves an equanimity and stability of mind which is in large measure responsible for the greatness of the nation.

The Casualty Lists

Another surprise was the relatively small number of casualties following upon bombardment. Pre-war esti- mates had mentioned anything from 30,000 to 150,000 as likely to follow one big raid. When the attacks were made they were certainly on a large scale, for on several occasions it was said that 300 or 400 bombers dropped their explosive loads upon the metropolis in one night; yet the number of casualties, while most regrettable, was on a much smaller scale than the most optimistic of prophets had ventured to forecast. The number for the country as a whole has been published, and we were told on one occasion that the casualties for London then com- prised about four-fifths of the total. Since then the pro- portion has been less great because several provincial cities have had severe attacks. From the figures officially announced a rough estimate can be made that during the 100 days of intensive attack there was a daily average in London of more than 100 killed and more than 150 injured.

This comparatively small casualty list was not due to the fact that the people were all in shelters, for the majority still elected to sleep in their own houses, preferring, as one woman said, "to die suddenly in our own home rather than die a lingering death from 'shelter pneumonia.'" The striking feature of the casualty list, however, is the high proportion of fatal injuries. It was fairly constantly found that about 40% of those sufficiently hurt to be termed casualties had been fatally injured—a proportion much higher than in ordinary battle, and requiring some explanation. The explanation is to be found in the age and condition of the victims, the nature of the injuries, and the number of factors which may operate in one case. A battle is fought by young men in good physical health, but civilian air-raid casualties include the old and infirm, and the very young and sensitive. In battle a single bullet or part of a shell may cause considerable injury without hitting a vital part, while in air raids one vital part at least is likely to be damaged by the common crush injury. Again, when people are caught in the wreckage of a house many secondary missiles are formed by fragments of the building. In addition there are the dangers of asphyxia from burial in debris or from inhaling clouds of dust, the peril of poisoning from escaping gas, the risk of fatal burning in the ensuing fire or scalding by steam from broken pipes, and there is the effect of severe shock induced by the pressure of heavy and not easily removable structures pinning down the victim.

Wounds due to Glass: Crush Injuries

I cannot here describe fully the various types of wound and the complications that may be encountered. I can only emphasize some points in respect of which the injuries due to bombardment differ in kind or degree from those customarily met with in civil or in military surgery. These differences depend for the most part on the large proportion of crush injuries which result from falling buildings, on the frequent occurrence of severe effects of blast from high explosive, and on the injuries from secondary missiles, particularly from fragments of glass.

Injury from broken glass can be very serious. The force of an explosion often breaks all the windows in the buildings around the site, and glass fragments of all sizes

are propelled in every direction at great velocity. Glass easily enters the tissues, but is not as a rule infective. Large fragments may do serious damage, and may need to be removed promptly, but in some cases innumerable small portions may become embedded, the removal of which is impossible or inadvisable. Some of these cases have developed anaemia a few days later, and have required blood transfusion. Perhaps it may be assumed that there were multiple small haemorrhages caused by some of the deeper fragments. Recognition of glass in the tissues by means of radiographs is fairly easy (see Fig.).

Radiographic illustration of multiple glass fragments in the arm (by courtesy of Dr. J. C. Davidson).

Injuries due to crushing of body or limbs by great masses of debris have constituted some of the severest lesions. This is not a question of a sudden crush which is soon relieved, but, as a rule, of a pressure continuing for minutes or even for hours before release. Fractures of limbs, pelvis, or spine, which ordinarily cause a great amount of shock, will in these circumstances depress the vitality to the limit of endurance or beyond it. One form of spinal fracture which I have not seen in civil work is a horizontal fracture through the bodies of several adjacent vertebrae, with little or no compression and only slight forward displacement of one or other fragment of the fractured bodies. In one or two cases there had been no suspicion of a fractured spine until routine x-ray examination revealed the state of affairs

Shocked Patients

As a rule there is no difficulty in recognizing that a patient is suffering from severe shock, but it is well to remember, what I pointed out as long as twenty years ago, that the classical symptoms of shock are not all present in any individual case. Recently Whitby (1941) and others, in a study of secondary shock as seen in air-raid casualties, have emphasized the same point of dissociation of shock symptoms. They rightly insist that the pulse rate may be dangerously misleading, that the mental state is no index to the severity of shock, and that the amount of sweating may be unrelated to the degree to which shock is present. I agree with Whitby and his colleagues that blood pressure is at present the most reliable measurable factor at our disposal for assessing the severity of shock, but I would add that in some cases the pulse pressure may be a better guide to the patient's condition. It may be that in the future we may obtain a better indication from the measurement of the blood volume or the specific gravity of the peripheral blood. A point not sufficiently recognized is that a degree of shock may exist before the systolic pressure falls, and that sometimes an apparently normal systolic pressure may coexist with a very serious state of shock. The most important lines of treatment for shock are rest, warmth, administration of morphine or omnopon, and the giving of plasma or blood transfusions, before disturbing the patient further by undressing, washing, taking radiographs, and, still more, by operative intervention.

Other Complications of Injuries

A new form of intestinal injury, caused by prolonged pressure on the abdominal cavity, has been discovered. In the case of a woman who lay helpless with a heavy beam pressing upon the lower part of the abdomen, subsequent exploration showed a state of peritonitis due to multiple points of gangrene in a coil of small gut lying in front of the lower lumbar vertebral bodies. Resection was carried out, but did not long delay a fatal issue. As there was no obvious lesion of the abdominal wall and no thrombosis of the mesenteric vessels, it is reasonable to conclude that the multiple points of gangrene resulted from the continuous direct pressure on the wall of the coil of gut. McMichael (in a personal communication) and others have recently described a very serious complication of severe crushes of the limbs in the shape of symptoms of profound shock accompanied by signs and symptoms of renal failure. Urinary output diminishes, vomiting and abdominal distension supervene, and the blood urea rises to a high level. In cases which came to necropsy extensive aseptic necrosis of the crushed limbs was found and the kidneys showed some tubular degeneration and blood casts in the collecting tubules.

The effect of blast is an important factor in air-raid casualties. The experiments of Zuckerman (1941) suggest that much of this effect may be due to the impact of the sudden pressure upon the exterior of the trunk, causing injury to the contained viscera. Surgically, the effect of blast on the abdominal cavity is of importance. Zuckerman, in experimental cases, has observed haemorrhage into the gut wall and even rupture of the bowel. Some confirmation of the experimental findings is given in the account by O'Reilly (1941) of five air-raid casualties which presented symptoms of acute abdominal disorder, and in which at operation some subserous haemorrhages were found but no major lesion. Mitchiner (1941) mentions a case in which he attributes rupture of liver and spleen to the effect of blast.

Clearance of Casualties

[In the last part of his lecture Mr. Zachary Cope recalled the inauguration of the Emergency Medical Service, the arrangements which were set up for distribution of casualties to hospitals, the division of London and the surrounding area into sectors, and the enlargement and equipment of outlying hospitals.]

The immediate medical treatment of casualties fell to the lot of the mobile units and first-aid posts. Doctors attached to mobile units were quickly on the scene of "incidents," and the work done by them in conjunction with first-aid squads has been in the highest degree praiseworthy. First-aid posts dealt with casualties as they were brought in, and the more serious cases were sent on to the nearest hospital. The view held by Trueta that first-aid posts should generally be in or attached to a hospital, where any necessary treatment can be performed, seems to have some support from London experience.

The effect of bombardment, with evacuation and blackout, was to diminish considerably the work of the general civilian practitioner. Patients did not throng the surgeries as in peacetime. Fewer beds were available in the central hospitals and many hospitals were hit by bombs, but a good out-patient service has been maintained. As for medical education, the pre-clinical students for the most part are out of London. Students doing hospital work have been distributed among the hospitals in the sector to which their medical school is attached. In some cases this has led to a closer relation between student and teacher, which is all to the student's good, but in certain instances regular teaching has not been easy to maintain.

In this rapid survey I have skimmed the surface of the subject; in due time many will write more fully of each

of its aspects. It is to the credit of the medical profession that its members, sharing ordinary civilian risks, stood to their posts of duty, which often involved great additional risks, with unflinching courage and resolution.

PSYCHOLOGICAL TERMS USED IN CASES OF HEAD INJURY

A glossary of psychological terms commonly used in cases of head injury has been drawn up by the Brain Injuries Committee of the Medical Research Council (chairman, Prof. E. D. Adrian) and is published by H.M.-Stationery Office as M.R.C. War Memorandum No. 4 (price 1d.). The object in view is to secure greater uniformity in case notes on such patients. Hitherto there has been no generally accepted definition of the words commonly used to describe the clinical effects of trauma upon the brain. The committee's notation, set out below, is already employed at the special centres for treatment of head injuries, and it is hoped that publication in this form may facilitate its adoption as a standard terminology throughout the medical services. The terms defined refer to the commoner psychological disturbances after head injury, but the list is by no means complete. The definitions are intended also to be useful for abbreviating description and for facilitating exchange of information between different observers. They are arbitrary and may not readily find universal acceptance; but since many of the words have in the past been used in varying senses, it seems essential, to avoid further ambiguity, that fixed definitions should be accepted and used. The prefix "traumatic" as used in this glossary denotes that the symptoms are due to the physical effects of head injury on central function; it may be added as a qualification to the appropriate term wherever applicable (for example, in "traumatic semicoma"), but its use should be obligatory for the terms to which it is attached in the list.

Glossary

COMA: A state of absolute unconsciousness, as judged by the absence of any psychologically understandable response (including, for example, change of expression) to external stimuli or inner need.

Note.—If a patient is comatose it is important to record the state of activity at levels of nervous integration lower than that which is the substratum of consciousness. Such activities are reflex—e.g., swallowing, pupillary and corneal reflexes, tendon jerks, plantar responses. It is not uncommon to hear it said of a patient who is comatose and cannot swallow that he is "deeply unconscious." This statement has no real value. He should be said to be comatose with loss of swallowing reflex.

SEMICOMA: A state in which psychologically understandable responses are elicited only by painful or other disagreeable stimuli—e.g., pinching the skin, shaking the patient vigorously.

CONFUSION (Clouding of Consciousness): Disturbance of consciousness, characterized by impaired capacity to think clearly and with customary rapidity, and to perceive, respond to, and remember current stimuli; there is also disorientation.

Note.—When a patient is said to be suffering from confusion the degree (see below) should always be specified.

Degrees of Confusion

Mild.—A state in which the patient, though presenting the characteristic features of confusion in some degree, is capable of coherent conversation and appropriate behaviour.

Moderate.—A state in which the patient, though out of touch with his surroundings, can be got to give relevant answers to simple questions such as "What work do you do?" "How old are you?" "Where do you live?"

Severe.—A state in which the patient, though for the most part inaccessible, will occasionally show adequate response to simple commands forcibly given and, if necessary, reinforced by appropriate gestures—e.g., "Put out your tongue," "Take my hand."

DELIRIUM: A state of much-disturbed consciousness (confusion) with motor restlessness, transient hallucinations, disorientation, and perhaps delusions.

TRAUMATIC STUPOR: A state in which the patient, though not unconscious, exhibits little or no spontaneous activity. In traumatic stupor there is always confusion.

TRAUMATIC AUTOMATISM: A state in which the patient, though capable of responding normally to his immediate environment, subsequently has amnesia for the period in question. In this state there is always some degree of confusion with disorientation.

CONCUSSION: A state of unconsciousness, or impaired consciousness, however fleeting, suddenly produced by mechanical force applied to the skull, and usually followed by retrograde amnesia.

TRAUMATIC DEMENTIA: Progressive mental impairment, predominantly of the intellectual functions, resulting from structural damage to the brain.

TRAUMATIC INTELLECTUAL IMPAIRMENT: Impairment of the intellectual functions which may be persistent or recoverable, but is not progressive, resulting from structural damage to the brain.

TRAUMATIC PERSONALITY DISORDER: Alteration of temperament and character which may be persistent or recoverable, but is not progressive, resulting from structural damage to the brain.

MALINGERING: Intentional simulation of symptoms.

HYSTERIA: A condition in which mental and physical symptoms not of organic origin are produced and maintained by motives never fully conscious, directed at some real or fancied gain to be derived from such symptoms.

Note.—The adjective "hysterical" may be applied either to this condition or to the type of psychopathic personality common among those who develop this condition, but it should not be applied—as is often done—to behaviour which is merely uncontrolled and emotional.

INSIGHT: Capacity for arriving at as objective and correct an estimate of any impairment due to one's illness as would be arrived at by a detached onlooker with equal access to relevant facts.

JUDGMENT: Capacity for arriving at reasonable conclusions, leading to well-adapted behaviour, especially as indicated by conduct in the practical affairs of daily life.

COMPREHENSION: Capacity to integrate diverse percepts and or ideas and to understand the relation between them and one's personal experience.

AMNESIA: Impairment of memory, however caused. It is most commonly applied to incapacity to recall particular topics or the happenings of a particular period.

EPSOM COLLEGE ANNOUNCEMENTS

We publish the following announcements regarding vacant scholarships for girls and a pension for a doctor, at the request of the Royal Medical Foundation of Epsom College.

Scholarships for Orphan Daughters.—The Council of Epsom College will shortly proceed to award St. Anne's Scholarships to girls attending Church of England schools. Candidates must be fully 9 and under 16 years of age, and must be orphan daughters of medical men who have been in independent practice in England or Wales for not less than five years. The value of each scholarship is dependent upon the means of the applicant and the locality and fees of the school selected.

Pension for a Necessitous Medical Man.—The Conjoint Committee of Epsom College will in May next award a "Christie" pension of £89 per annum to a necessitous medical man, fully 55 years of age. Candidates must be duly qualified, and have been registered for five years.

Forms of application can be obtained from the Secretary, Epsom College, Surrey, and must be completed and returned by April 25, 1941, at the latest.

MEASURES FOR CONTROL OF LICE

In a leading article in the *Journal* of February 8 (p. 199) on lice and disease we referred to an investigation undertaken by Mr. Kenneth Mellanby at the request of the Minister of Health and the President of the Board of Education into the incidence in England of vermin infestation, particularly by head lice. The two Departments have now issued a joint memorandum to local authorities and their medical officers of health, which, after summarizing the scope and findings of the investigation, indicates the action which the authorities should take, and reminds them of the powers they have, to secure a reduction in the incidence of verminous conditions.

Findings of a Survey

Mr. Mellanby's survey, the memorandum states, was based on some 60,000 cases in hospitals—mainly infectious diseases hospitals—in industrial cities having a population of about 400,000, in rural counties, and in two Midland counties, one of which has a mixed rural and industrial population. It showed that: (1) a very high degree of infestation with head lice exists in the industrial cities, but that body infestation is rare; (2) girls are more frequently infested than boys; (3) the highest incidence is found in pre-school children; (4) the percentage of children infested is very low in rural counties; (5) in industrial cities infestation in girls reaches a peak at 3 years (51.6%) and remains round about that level until the age of 14, while in boys it declines steadily with age after the peak is reached in the fourth year; and (6) the percentages in the industrial cities on the average are three times those shown in the reports of school medical officers. These findings once more indicate, the memorandum continues, that it is to districts in which housing and social conditions are unsatisfactory that the main weight of any campaign to eradicate verminous conditions must be directed.

Education the Key

Mr. Mellanby concluded that education of the public was the only method likely to give permanent success, and the memorandum indicates the lines on which this should be undertaken. First, children once cleansed should not run the risk of reinfestation at home, and the public generally, but especially mothers, should be taught the importance of clean heads, not only to the health and comfort of the child, but to their own social credit. School children, particularly the girls, who will be the future mothers, should be taught the same thing, school teachers if necessary getting the help and advice of school nurses or similar persons. There should be a more thorough examination of heads in schools, and if school nurses cannot devote further time to this part of their work local authorities should consider whether it could be done by less highly trained persons under the supervision of the nurses. Advice should be given in articles and talks on health, and all persons known to be verminous should be told how they can rid themselves of the trouble and avoid it in future. Frankness and discretion are needed, because it is known that progress has often been hampered by attempts to conceal or deny the existence of a condition which may be regarded as detrimental to the individual.

Education authorities, the memorandum continues, already have the power to direct the medical officer of health or person authorized by him to examine any child at any elementary school and require the parent to cleanse him (in accordance with written instructions) within twenty-four hours, or, if the parent fails to do this, to remove the child for cleansing. Local authorities have power to provide cleansing stations, to cleanse persons applying to them and their clothes, and, in London, compulsorily to examine inmates of common lodging houses and order cleansing. The memorandum concludes by saying, however, that improvement will be secured not by resorting to compulsion, but by using to the full the administrative measures available for dealing with cases that arise, and preventing recurrence by intensive education of the public.

DISTRIBUTION OF AIR-RAID CASUALTIES

This article on the distribution of casualties to hospital is written by a surgeon who has recently visited heavily bombed cities.

For the person injured in an air raid the ideal medical service would be one which was conducted under one control from the moment the patient received his injury to the time of his return home completely convalescent. If such an arrangement were in force, it would not be difficult to decide the "saturation point" for any given hospital, the organization of ambulance services, the instructions to be given to drivers, and the delivery of casualties to the best advantage to all concerned. The present state of affairs arose because one part of the A.R.P. services is under the control of one Ministry and another part under another. The fire brigades and the police are, of course, the direct responsibility of the Home Office, and it was perhaps natural that the warden service, because of its semi-police functions, should come under the same authority, which also recruits and for the most part trains the rescue squads and stretcher-bearers. Decontamination squads are employed by local authorities. Local or scheme-making authorities—as, for example, the L.C.C.—were already before the war responsible for the ambulance services. The Ministry of Health controls first-aid posts and, indirectly, ambulances. Its contact with the first-aid parties is through the medical officers of health, who, while under scheme-making and local authorities, look to the Ministry for guidance.

Now experience has shown that rapid admission of casualties to hospital depends upon the co-ordinated effort of the entire A.R.P. service: a quick report by the warden; action by the police to clear the way for all services; priority for the fire brigade and the rescue squads; competent direction of first-aid parties by the incident doctor; skilful deployment of ambulances under the direction of the incident officer, and clear instructions to the drivers. This chain must be perfect in every link.

No one person at a single incident can have a complete picture of both this and the other events that may be happening simultaneously. Sometimes confusion may be so great that even Central Control may not be able to obtain a clear picture of the situation, but it alone can determine the best distribution of available resources, decide when to call for further assistance, and assume the ultimate responsibility for diverting ambulances from a hospital which is approaching saturation point.

Operating Capacity of a Hospital

With these facts in mind, and in the light of actual experience, it is now possible to consider the hospital problem itself. Originally the number of vacant beds was considered to be the measure of the capacity of a hospital, a conception that for some time dominated the organization of the ambulance service. Long before the beginning of severe air raids, however, surgeons pointed out that no more stretcher cases ought to be admitted to a hospital at one time than can be deliberately operated upon within six, eight, or, at the very most, ten hours, and the conception of what a hospital's capacity is was modified. Within the first eight hours bacteria in a wound remain, broadly speaking, "on" rather than "in" the living tissues, and are thus susceptible of removal by the customary surgical toilet.

How many cases can be dealt with on one table within ten hours or, preferably, within eight or six? It is safe

to say that in the last war, apart from the treatment of "walking" cases, the average table, continuously manned, did not operate on more than twenty-four cases in twenty-four hours. No doubt this number was exceeded on occasion, but it may be safely taken as the limit for the average theatre capacity. Thus a four-theatre hospital should not admit more than forty or fifty cases at a time (not all will need operation, so a margin may be allowed), and a two-theatre hospital twenty-five. When this capacity has been reached the hospital should "switch"—using the arrangements already existing and now to be codified—to ensure that further casualties are diverted to other hospitals.

Switching

The present mechanism for switching is complicated, and differs in different localities. The following methods have been employed. A hospital, when full, has simply shut its gates, stationing someone to advise arriving ambulances to go to the next hospital on the list and to report back to the Incident Officer. This method is open to serious misunderstanding and has led to bitter recriminations. Moreover, not all ambulance drivers have lists of hospitals to be used in succession as necessity arises. The Medical Superintendent or Medical Officer in charge of a hospital has made his contact in various ways. He has communicated by telephone with his Hospital Officer (in Region) or Group Officer (in Sectors). He has sent word to the nearest Report Centre, Sub-Control, Control, or to an ambulance group superintendent, or even direct to an ambulance depot. Messages have been sent to police, and even to fire-brigade, stations when it is known that they are close to a depot that cannot be reached direct. Hospitals have approached other near-by hospitals direct, and warned them that cases are being diverted to them. Unfortunately, telephones often break down, and though in some places the private police lines may be available when the general system fails, it is often absolutely necessary to use messengers. Messenger services have frequently proved quite inadequate. Whatever the system ultimately adopted, every hospital should know the procedure current in its own area, and meanwhile every method for utilizing the utmost capacity of its own resources should be known and practised.

Relief Surgical Teams

For instance, if all the available tables cannot be manned from the available staff, the assistance of visiting teams should be sought. These "supplementary" teams will have at their disposal all the routine facilities of the hospital—for selection of cases and their transport to and from the theatre, supplies of sterilized dressings, clothes, instruments, solutions, anaesthetics, etc. Alternatively it may happen that there are too many patients for the number of tables and that transfer is impossible. Then the visiting team may properly be summoned to "relieve" the original teams, who may tire before the work is completed. Or relief may be necessary when one raid rapidly follows on another and the regular theatre team has practically no rest between the two.

It is no use summoning relief teams unless the accessory services are in a condition to function. It is not only the surgeons, their assistants, and the theatre nursing staff who tire. All the active members of the hospital organization—the ward staff, the dispensers, the laboratory staff, the x-ray technicians, the linen-room attendants, the kitchen staff, the sterilizers, bearers, porters, clerks—all may have been overworked and require to be relieved. It has happened that visiting teams have arrived to find a whole staff exhausted, falling asleep, or actually asleep. Most hospitals have grown accustomed to sending requests for blood and plasma, but some of them still consider it a reflection on their efficiency if they make similar requests for sterilized dressings, surgeons' aprons, A.T.S., or sera and other supplies. All these can be made available in an emergency.

Preparations for Relief

It is important that the medical officer in charge of every hospital should, in times of stress, anticipate the moment when his organization will need rest, and that he should summon help well in advance of that moment. Matrons, too, should be ready to ask for relief nurses from a central pool or from another hospital. The medical officer should make sure that when surgical help arrives there will be enough still fresh members of his own resident staff for the rather delicate task of making the visitors at home with the routine of the hospital, and for giving all the help (and a little more) that they are accustomed to give their own surgeons and physicians. Visiting teams, which often arrive after difficult and sometimes dangerous journeys, have at times had cause to complain of their reception. It is true that they may not always have visualized the trials to which the visited hospital has been subjected; but more often than not they are of course fully aware what these are. Nevertheless, a visiting team has a right to expect to find a ready-made plan for its reception. Surgeons, housemen, and sisters will need to receive immediate instructions and information from their corresponding colleagues at the hospital. A member of the senior staff, perhaps a physician, should give the visiting surgeons full information about the patients who are waiting to be treated.

When continuous or severe raids lead to some inevitable disorganization, the more self-contained a visiting team is the better. In addition to anaesthetist, assistant, and sister, it is of great advantage if the team also includes students and/or auxiliary nurses, who can act as orderlies to fetch, carry, make inquiries, take notes, etc.: if it also arrives with its own instruments and sterilized supplies, so much the better. Before the operating theatre is available the relief team may be needed to help by examining admissions, selecting cases for priority, preparing them for operation, carrying out blood transfusions, undertaking immediate post-operative management of patients just off the table, and generally performing duties which normally are left to juniors. If two relief teams arrive simultaneously, one may offer the help just described whilst the other operates, with interchange of duties at a later period.

Further Points

The task of the visiting team is greatly simplified if the receiving hospital has set aside a reception ward adequately cleared for resuscitation. This should be possible in all but the smallest hospitals, and the value of such a ward has been so fully proved that the normal prescriptive rights of a surgeon over his own ward should not be allowed to stand in the way of securing a reception ward at all costs. Whether the hospital has one man always in supreme charge or not, the reception ward should be in the charge of a senior surgeon experienced, if possible, in war work at a C.C.S. If the work of the reception ward goes smoothly, then half the battle is won.

Clear plans, giving exact details, with names, dates, and hours, should be posted in every casualty receiving hospital in the country. During a raid the surgeon in charge of the team on duty should have complete charge of the hospital and be able to make use of any wards, whether they are under his care or not. The second team, with its surgeon, should be on call, while the third team, if not

required, should be available to send to the assistance of another hospital needing it. Visiting physicians and specialists and additional surgeons should all find some place in the composition of the teams.

The whole A.R.P. system is founded on the idea of mutual support. In general it has worked extremely well, but, as was to be expected, experience has revealed loopholes in the organization of various departments. As has already been stressed, the principal fault is failure to make preparations in advance down to the smallest detail, and this applies to the reception not only of relief surgical teams but of police, firemen, rescue and stretcher parties, ambulances, mobile units, and so forth, which have to be met, distributed, housed, or sheltered. Failure in preparation often means that the heads of the various services have, during their urgent duties in a raid, to be called away to improvise arrangements that should have already been made.

Hospitals that have adopted the principles outlined above and have perfected their plans have successfully undertaken arduous work under the most adverse conditions. When such hospitals put in a call to be switched, then their request will be accepted without question; when the hospital is once again ready to receive casualties it must inform Control of this fact. Here it might be added that no hospital should be reluctant to send out a relief team on the grounds that in their absence it might itself be damaged in a raid, as it is obvious that it will have its one or more basic teams in reserve.

The lesson of all this is that the work must be done at the spot where it is needed, no matter who does it.

AIR-RAID PRECAUTIONS

The February issue of the bulletin *A.R.P. Progress*, published by the National A.R.P. Co-ordinating Committee, 30, Bedford Row, London, W.C.1, summarizes recent progress in our preparedness against air attack and gives some useful information about gas—information which should certainly be more generally known.

Precautions against Gas Attack

The following are the main types of gas attack which may be expected: (1) Non-persistent gas or smoke released from planes either by bombs or by generators. (2) Persistent gas sprayed or scattered from low-flying planes, or dropped in containers. (3) Clouds of gas or smoke released from ships (this would be possible over the South-East and as far as London). (4) Gas from shells, tanks, or grenades if troops are landed.

Because the enemy is nearer, and especially because people have become careless about gas masks, such methods of attack are at present more likely to be successful than at the beginning of the war. They might be used to cause disorganization, since a heavy attack of mustard gas would compel wholesale evacuation from the areas affected, these areas remaining unsafe until they had been decontaminated either naturally or artificially. Alternatively gas might be used simply as a means of destruction and to bring about panic. As surprise would be an important factor, such an attack would be made in the first place on a large scale. The public cannot be too strongly urged to carry their masks with them wherever they go, especially at night, when a large-scale attack would be most probable. In the House of Commons on March 27 Mr. Herbert Morrison said: "The Government are taking fresh steps to ensure that every member of the population carries, practises with, and is in every respect familiar with the use of his gas mask. The authorities responsible for the periodic inspection of gas masks should be punctilious in their duties. Although in some areas inspection is frequent and efficient, there are some vulnerable parts of the country where it is not carried out at all.

The *Bulletin* advocates proofing all shelters and Tube stations. It is pointed out that large, well-designed shelters can be easily gas-proofed, whereas small ones are on the whole more difficult.

It is recommended that the following facts should be impressed upon shelter marshals and on the public: (1) that an ordinary room with windows shut and chimney packed gives considerable protection; (2) that the danger of suffocation in shelters from vitiation of air by breathing is negligible, since overheating of the air and panting would give ample warning; (3) that there is extreme danger of bringing liquid mustard gas or gas-generating substances into shelters or houses on boots and shoes; (4) that the civilian gas masks can be relied on.

Table Shelters

The National A.R.P. Co-ordinating Committee is unfavourably disposed towards the new indoor "table" shelters. The Government itself has said[1] that indoor sectional steel shelters would take up space increasingly needed by the bombed and homeless; that they "provide no additional protection against splinters beyond that which the walls of the room provide"; that they might well be driven through the floor or displaced by the weight of the collapsing house, or the exit from them might be blocked by falling masonry and those within might find themselves trapped and threatened by fire or escaping gas. The Co-ordinating Committee points out that these objections apply equally to the table shelters. Protection in them is below "code standard," since house walls are commonly of 9-inch brickwork, while the standard wall for a surface shelter is 17½ inches. Moreover, it is impossible to gas-proof these shelters. Most important of all, they use up steel which is badly needed for other purposes, particularly for the construction of heavy shelters.

The committee's criticism is not destructive only. It believes that an indoor shelter could serve a useful purpose in scattered areas where the communal shelter may be far from home. Home Security Bulletin C.14 describes a good indoor shelter with a cross-braced framework independent of the structure of the building, supporting a canopy which would catch falling debris. It is recommended that in any case windows and doors should be provided with baffle walls as a protection against splinters, that there should be an emergency exit, and that the room chosen should face soft ground to avoid damage from concrete which an explosion might throw up in splinters. A room prepared in this way could be used for other purposes.

While the new fire-fighting arrangements are justly praised, two dangers are emphasized—that of reduced output owing to the extra hours and strain, and the difficulty of protecting fire-watchers while they are on duty. Some kind of protection even against shrapnel and splinters would be a help.

The problem of fire-fighting, like the earlier one of utilizing the Tubes as shelters, has been met by sheer force of circumstances. But in less obvious matters—urgent though they may be—officialdom is still adopting, the *Bulletin* states, a blundering, half-hearted policy. The Board of Education states: "Damage to schools has been almost wholely confined to the hours of darkness when children are not at school, and this is a factor which is clearly relevant to the consideration of the type of protection to be provided." Building of shelters is still talked of as in some instances "impracticable," to be supplemented by the admittedly makeshift method of scattering school children to neighbouring houses during an alert. The Co-ordinating Committee, on the other hand, has prepared drawings of a modified "Haldane" shelter—class-rooms by day, safe shelters by night. Drawings can be obtained from the committee at 1s. 6d. each post free.

Local News

ENGLAND AND WALES

Country Branches of London Hospitals

St. Thomas's Hospital and Guy's Hospital are both opening country branches within the next few weeks, the former near Godalming and the latter near Sevenoaks. The country hospital of St. Thomas's will have 350 beds, about 100 beds being retained in London to meet emergencies; the out-patient department and various clinics will also be on the old site. The medical school will in the main follow the hospital into the country, the students being accommodated a few miles away in an old manor house. The hospital itself is built on the hutment plan, and nurses and other personnel will also, as a wartime measure, be lodged in huts. It is intended to have a special ward in which children suffering from air-raid injuries may be treated. The magnificent block of St. Thomas's, south of Westminster Bridge, which was opened by Queen Victoria exactly seventy years ago, suffered severely in the early air raids, and the damage to buildings and equipment has been estimated at over £1,000,000. Guy's has not actually suffered severe damage to the fabric, but surrounding property has been destroyed and the hospital income from property rents has dropped by about £12,000 a year as a result. A gift of $10,000 has been made by the American people for the equipment of the country branch, and it is hoped to commemorate this gesture in the name given to the hospital. The hospital in London will be maintained with 180 beds for civilian sick, apart from 200 reserved for air-raid casualties, and full out-patient facilities. If the hospital services should be seriously handicapped by further severe bombing in the neighbourhood an immediate switch-over will be made to the country branch. Both hospitals emphasize that this is not necessarily a wartime measure, but may be the beginning of a development of the large central voluntary hospitals to be continued after peace returns.

SCOTLAND

Polish School of Medicine in Edinburgh

A Polish School of Medicine was inaugurated at Edinburgh University on March 22, Sir Thomas Holland, Vice-Chancellor of the University, presiding. The school is being provided for the Polish Government by the Senatus of the University, and the first beneficiaries will be men who completed their studies in Poland but who, because of the war, did not sit for their final examination. The academic ceremony was attended by the President of the Polish Republic (M. Raczkiewicz), upon whom was later conferred the honorary degree of Doctor of Laws. Sir Thomas Holland referred to the occasion as unprecedented in the history of universities. Although wars and invasions had occurred in every century, he said, never before since the rise of universities five or six hundred years ago had these seats of learning in any country been ruthlessly destroyed as had happened during the present war in Poland. With the revival of learning in the Middle Ages the universities were founded as *studia generalia*, institutions to which scholars were welcome from all countries. Among the first to be founded was the University of Cracow [actually the oldest university in Central Europe, established in 1364], which had now been destroyed, but which would rise again as a nursery of truth for all peoples. He referred to the great names associated with the university, including, among the scientists, Copernicus and Marie Curie. Now in Edinburgh, around the nucleus of fewer than a dozen professors and forty-six students, there would grow up a Polish School of Medicine which, when it returned to its own land, would inaugurate a new era as the foundation faculty of the rejuvenated universities of Poland. President Raczkiewicz expressed his gratitude, and Prof. Sydney Smith, Dean of the Faculty of Medicine in Edinburgh, welcomed the fellow members of a great profession imbued with common ideals of service for humanity and a common quest for truth, to which a suitable reply was made by Prof. Jurasz, Dean of the Polish Faculty of Medicine. Later in the day a civic reception was given by the Lord Provost, when again the Polish President spoke. This new departure at Edinburgh has been the subject of negotiations for some time past. There are a number of Polish medical professors and lecturers in Scotland, some of whom were already professionally engaged in the laboratories of the University, and some Polish students, both men and women, have been attending classes.

Glasgow Municipal Hospitals

The Glasgow Corporation has unanimously approved a scheme proposed by the medical officer of health for the city whereby the municipal hospital facilities would be reorganized. The scheme provides for a change in the control of admission to hospital by granting the public health department powers to use these institutions for general treatment instead of confining their facilities to Poor Law patients. This important reorganization will complete the process of transferring all the municipal general hospitals in the City of Glasgow from Poor Law to public health control. Fifteen hospitals, large and small, are affected by the administrative change, which will take effect when the scheme has received approval from the Department of Health for Scotland.

Reports of Societies

DYSPEPSIA IN THE FORCES

At a meeting of the Section of Medicine of the Royal Society of Medicine on March 25, with Sir MAURICE CASSIDY in the chair, a discussion took place on dyspepsia in the Forces.

Colonel H. LETHEBY TIDY divided the subject under three headings: (1) peptic ulcer; (2) functional dyspepsia; (3) transient dyspepsia. Was the amount of dyspepsia in the Army larger than in civilian life? Payne and Newman investigating Army cases in the early part of the present war found that 92% of those affected had had symptoms before joining the Service; a more recent examination of the records of a hospital by Graham showed that of the patients with peptic ulcer 94% had shown symptoms in previous civil life. Only a trifling number of cases of peptic ulcer had developed in the Army. He drew attention to the great increase in dyspeptic conditions in the population generally during the last twenty years; he thought the profession had been somewhat remiss in not recognizing this increase. At the same time, relapses seemed to take place more quickly under Army conditions, owing partly to Army food and cooking. Army diet was more liberal and heavier than that to which the mass of the civil population was accustomed, and was undoubtedly a satisfactory diet to healthy men not previously subject to dyspeptic disturbances. As for cooking, there were deficiencies in the early months of the war, but it had been improved out of all knowledge, and still this rapid relapse of cases with organic dyspepsia occurred. He was convinced that these men would have relapsed just as surely whatever the diet and whatever the cooking. A menu chosen by Lucullus and a meal cooked by the chef of the Ritz would not have prevented relapse. Army routine was not compatible with the maintenance of continuous health in men who were subjects of chronic dyspepsia. It must be remembered that a relapse in the Army meant one thing and in civil life another. A man in civil life who felt any recurrence of his old trouble laid up at home for a day or two on a milk diet, but the man in the Army had to go into hospital and thus became officially a case of relapse.

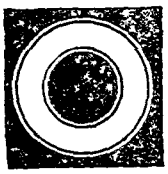
Psychological Factors

Colonel Tidy next went on to speak of the psychological factor. The conclusion of some recent investigators was that in

the majority of these cases in the Army there was very little psychological disturbance. The cases of peptic ulcer seen in hospital tended to lose their symptoms with striking rapidity on dietetic treatment alone, and psychological disturbances did not appear to delay recovery. The kind of psychological factor which might be expected to operate was worry about business and separation from family; on the other side the men had the great relief of security of occupation. All the psychological factors operated in the last war (except large-scale bombing in this country), when the incidence of peptic ulcer and organic conditions of the stomach was reduced. The Registrar-General's returns of mortality showed, in respect of death from peptic ulcer, a flattening of the curve during the war period, the curve rising again after the war. There was no evidence that psychological or any other kind of disturbance increased the incidence of these conditions during the war.

Turning to the large number of cases of gastritis, Col. Tidy said that these, on the whole, were far more resistant to treatment than were those of peptic ulcers, and there was more likelihood of a psychological element in them. In the early months of the war it was supposed that these cases could be dealt with by marking the men down to a lower category, but they relapsed or their symptoms continued as definitely in category "C" as in "B" or "A." Yet many of them carried on and made useful soldiers. When they went back to their units it was the duty of the medical officer to keep them there if he could and for as long as he could, but if he failed they must go back to hospital. When these men had been twice in hospital they should be boarded out. They ought to have a second trial, and the medical officer should do all he could to keep them in the unit. He might, however, be faced with impossibilities. If a man vomited over the dinner table the M.O. was helpless, and it was astonishing how many of these men did vomit, owing to an unexpected appetite from the morning exercise and the temptation to eat a hearty meal.

Finally, there were the transient dyspepsias, which might affect healthy men on finding themselves in a very new environment. It often happened in the training centres that men reported sick with transient dyspepsia within a fortnight of joining the Service. If the M.O. was wise and experienced he would reassure them and give them a bottle of medicine (without the bottle they might be considered to be malingering). But if he was weak and inexperienced he would send the case to the hospital physician or a specialist, and if the latter lacked confidence he would admit the case to hospital. These men recovered or lost their symptoms very quickly and were sent back to their unit as "cured"; but they were not acclimatized, and soon the cycle started all over again. It was almost true to say that if a man was twice in hospital with the same complaint he was unlikely to develop subsequently into a useful soldier; he was converted into a case of almost incurable gastritis, and was actually more difficult to deal with than the cases of chronic gastritis in which the sufferers had over a course of years learned to deal with their disability. Cases of this group of transient dyspepsia ought not to be seen largely in hospital. It was extremely easy for medical officers—lacking rather in confidence than in competence—to magnify and multiply these cases.



Differential Diagnosis

Dr. CHARLES E. NEWMAN said that three or four definite problems came up for discussion. One of them was the diagnostic problem of distinguishing duodenitis from duodenal ulcer: the choice between these two seemed to depend upon the preference of the local school of radiological thought. But surely they were all accustomed in civilian practice to diagnose peptic ulcer with negative *x*-ray appearances. In a reasonable percentage of cases gastroscopy revealed an ulcer which was not seen by *x* rays. Occult blood in the faeces was a valuable guide, though not a valuable negative finding, in the diagnosis of ulcer. Another problem was the ascertainment of an organic as distinguished from a neurotic condition. Psychological factors were very important in the causation of gastric disturbance, but many people thought of them in a loose way. Worry was regarded as a psychological trauma, and yet it was the common lot. A girl who had an illegitimate child was put down as suffering from psychological trauma, though to a strong-minded girl it would be not a psychological trauma but a physiological event. The assessment of the psychological factor seemed to him often very superficial. In many of the organic cases there was a neurotic element. The person suffering from gastric ulcer was usually rather abnormal in his mind—as, for example, Thomas Carlyle, than whom a more rampant neurotic could not be imagined. What really mattered was to find out whether one or both conditions existed and to treat both if both were present. He pleaded for some settled order in the examination of gastric patients; otherwise everything depended on the view which the examining doctor took of such cases. For some doctors they had a fascination, others regarded them with impatience. Unless handled by someone who had an interest in them the patients were not going to get a "fair deal." For some reason the Army liked the diagnosis "gastritis." This was the predominant diagnosis of patients sent from the B.E.F. last year. Fifty years ago gastritis was well recognized as a common disease, but with the coming of more accurate means of diagnosis it became not only unpopular but the last gasp of the destitute. With the advent of gastroscopy "gastritis" was reintroduced, but it was still not possible to say what was the normal and what constituted a departure from it. There was such a thing as gastritis, but it was a rare disease, and the vast majority of patients who formed this difficult group in civilian practice were not really cases of gastritis at all. Recently there had grown up a tendency to describe dyspeptic soldiers as suffering from "soldier's stomach," rather on the analogy of "soldier's heart." It was a term that did not mean anything at all.

Major J. G. SCADDING described an investigation into 137 cases of dyspepsia in the Army. In the large majority of cases the symptoms had started in civil life. Of fifty-seven in the proved ulcer group only six had their first symptoms during Army service; forty-one had had no operation. There was some difference between officers and other ranks; of the ten officers included among the 137 cases, as many as seven fell into the proved ulcer group. The average age of onset in this group was 26; in fourteen cases the symptoms had arisen before the age of 20. There was complaint of vomiting in 30% of the proved ulcer group, though in none was it the principal complaint, but in seventeen of the remaining eighty cases vomiting was the principal symptom. The psychoneurotic element was very difficult to assess. In only nine was an obvious psychological abnormality detected. How far this psychological element was favoured by the advertisements of patent medicines must be left to the imagination. Some of these advertisements were masterpieces of reversed psychotherapy.

Incidence of Peptic Ulcer

Sir ARTHUR HURST mentioned some remarkable differences between the incidence of ulcer in soldiers and in civilians. In private practice duodenal ulcer was about four times as frequent as gastric ulcer, though in hospital practice this did not obtain (in three of the large London hospitals the statistics, both clinical and post-mortem, over a good many years showed an equal incidence of gastric and duodenal cases). In the Army, apparently, duodenal ulcers were in the large majority. During the last year, working at Oxford, he had seen almost every gastric case admitted to the Radcliffe Infirmary; more than half were admitted on account of haemorrhage, but he understood that haemorrhage was extremely rare (under 5%) in Army cases. He wondered to what extent radiological evidence might be misleading. He saw a patient 35 years ago with the classical symptoms of duodenal ulcer; he got well under medical treatment and had no recurrence. Recently he saw him again for lumbago, when the patient told him he had never suffered from indigestion for the last thirty years but, to satisfy his curiosity, he persuaded him to have a skiagram taken, and the radiologist, who had been told nothing of the history, reported, "This man has duodenal ulcer." In how many soldiers was the old scar taken to mean an active condition? He wished there was some arrangement between the Army and the civilian hospitals for continuation treatment so that men discharged from the Army with their

CLIMACTERIC SYNDROME RELIEVED

"High Doses of Oestrin are usually unnecessary, at any rate for the commoner menopausal symptoms — such as vasomotor disturbances—and consequently oestrin injections are, fortunately, seldom required. It has been my practice to begin with doses of about 500 I.U. daily by mouth. If this does not control the symptoms the dose is raised to 1,000 . . . this is usually completely effective. There are, of course, certain more severe sequelæ of the menopause, which demand much higher doses . . . Pruritis, Kraurosis, Leukoplakia vulvæ, fall into this class and, provided sufficiently high doses are given, the results are little short of miraculous."

★DAGENAN SODIUM— M&B 693 SOLUBLE★

★TRADE MARK

This product is intended to meet the occasional need for a parenteral form of administration of DAGENAN—M & B 693.

Indications for injection are three :—

1 *Incapacity to take ★DAGENAN—M & B 693★ by mouth.*

2 *Failure to obtain an adequate blood concentration with oral administration.*

3 *Necessity for obtaining maximum effect as rapidly as possible.*

DAGENAN SODIUM—M & B 693 SOLUBLE will replace DAGENAN—M & B 693 in oil suspension which was introduced to meet the necessity of a product for injection before DAGENAN SODIUM was evolved.

Supplies { DAGENAN SODIUM—M & B 693 SOLUBLE
Boxes of 6 x 3 c.c. (1 gramme) ampoules at 8s. 0d.

litions could be returned as soon as possible to civil loyment. A great effort ought to be made to come to a clusion as to which cases had gastritis and which had ous dyspepsia. In true gastritis a considerable proportion ases in hospital, on a strict diet and morning lavage, would and remain well; the prognosis in true gastritis was quite d. He entirely agreed about the most undesirable way which some of these dyspeptics were sent again and again hospital. It was this kind of thing which during the last gave rise to D.A.H. Cases of disordered action of the rt were comparatively rare in this war, but there seemed be some risk of a new disease—" D.A.S."

ieut.-Col. S. J. HARTFALL said that the incidence of a rotic condition among the dyspeptic patients under his ervation at the present time was about 60%. That did mean that they were cases of neurotic dyspepsia, but e were *quite a number which had ulcer—or had had ulcer* viously—and had manifest neurotic symptoms associated i it. He also said that in a group of eighty-nine cases of pepsia with negative indications for organic disease on y, occult blood, and test meal examinations, 60% were entirely negative on gastroscopic examination, and 20% a superficial patchy gastritis, sometimes fairly diffuse but very serious—the sort of condition that would respond mirably to rest in bed with gastric lavage. The remainder wed positive findings and included some cases of acute tric ulcer missed by the *x*-ray examination, and a larger nber of chronic gastritis with atrophic or hypertrophic nge.

Mr. R. T. PAYNE said that there was no doubt as to the ike with which many medical officers viewed these gastro-odenal cases. The sufferers were put down all too easily malingerers. In some investigations which he with Dr. wman conducted in the early part of the war very few lingerers were discovered. In that same investigation much dence was found of surplus movement of patients between spital and unit. Many mistakes in diagnosis were made ing to the ascertainment being left to the radiologist or someone who had not the benefit of all the data. The stroscope would help to elucidate some of the more difficult d obscure cases, though not all; it would help in particular resolve the big group known as gastritis. He was inclined quarrel with that word, and also with the large proportion cases assigned to this group by various observers. Colonel B. MARSH spoke as a Regular Army physician whose prac-e in the Army dated back from before the last war. The st thing that struck him at Aldershot in the early days was at the age incidence in gastric cases (which he found to 19 to 22) was much earlier than was stated in the litera-re (30 to 35). With regard to gastritis, he became accus-med to dividing the sufferers into two categories: the beer-inkers and the bun-eaters. In the old Army days the er-drinkers formed the larger group; now the bun-eaters ere in the majority. He had never heard the term "soldier's omach"; it was not an Army term. He added that in North-est India the young British soldier did not get ulcers, either uodenal or gastric. In five years in that part of the world came upon no more than two cases.

Colonel TIDY, in reply, said that while the term "gastritis" as not of his invention, he thought it as good as any, and obody had suggested an alternative. He deprecated the term soldier's stomach." The cases which went back time after me to hospital were more aptly called "hospital stomachs" ian "soldiers' stomachs." As to the proportion of duodenal lcers to gastric ulcers, on looking up the returns at St. homas's Hospital for a recent year he found that more gastric lcers were admitted than duodenal. In the Army the statistics aried between four or six cases of duodenal to one of gastric lcer. Another term for which he had no use was duodenitis"; he would include cases of this description for rmy purposes (though not for scientific purposes) as uodenal ulcer. One radiologist would constantly diagnose uodenitis where another would diagnose ulcer. On the sub-ct of malingering, he felt confident that the amount of alingering in the Army was practically negligible, but there as some exaggeration, especially among men who went into ospital over and over again. Such men were very unlikely be useful soldiers.

EPIDEMIOLOGY OF PULMONARY TUBERCULOSIS IN THE ROYAL NAVY

At a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on March 28, Surgeon Rear-Admiral S. F. DUDLEY introduced the subject of the epidemiology of pulmonary tuberculosis in the Royal Navy, especially as regards the use of miniature radiography in its elucidation.

He said that pulmonary tuberculosis had always been an occupational disease of sailors. From the beginning of the century until the present time the invaliding rate for pulmonary tuberculosis had fluctuated around 2 per 1,000. During a period in which, judged by mortality statistics, tuberculosis in England and Wales had been nearly halved, the prevalence *of tuberculous disease in the Navy had remained unchanged.* This was due to the factor of population density, which could not be eliminated or even reduced in the Navy. The purpose for which a warship was designed prohibited any increase of deck space per man, and more and more men were required to work the complicated machinery. A yearly incidence of 2 per 1,000 seemed to be the irreducible minimum. This was double the figure prevailing in the Army and the Air Force, although the Navy had a larger proportion of boys and men at those younger and older ages which in civil life showed a lower incidence of pulmonary tuberculosis than the average. The closeness of community life on the quarter-deck was the determining cause of tuberculosis among naval ratings. The yearly incidence among naval officers was less than 1 per 1,000, and they nearly always slept in separate cabins and their living accommodation was more spacious. When men were promoted to officers from the lower deck, the rate of tuberculosis among them dropped from 2 to 1 per 1,000.

Miniature Radiography for Mass Examination

All men in the Navy suspected of having pulmonary tuberculosis were at once examined by *x* rays. But it was the unsuspected cases which must be considered. Little effect on total incidence could be expected from the *x*-ray examination of recruits or limited numbers of contacts, and periodical examination by *x* rays of the total force by the usual technique was considered impracticable. Therefore mass examination by miniature photo-radiography had been introduced as a less cumbrous and expensive proposition, and the Lords of the Admiralty had given permission for the installation of the necessary apparatus and staff at the three main naval depots. Once the scheme was in full working order the chests of all men in the Navy would be examined at least once every three years. No man would be labelled tuberculous on the evidence of a miniature film until a full-size film had been taken; the function of the apparatus was to pick out as quickly and economically as possible the cases which showed abnormal shadows in the lungs.

Of the first 18,000 cases taken, about 7,000 of the subjects were trained men, the others being new entrants. The numbers re-examined and the results of the examination were as follows:

	Re-examined (Full-size Radiograph)	Percentage Re-examined	? Active T.B. (per 1,000)	Active T.B. Established
Trained men ..	269	4.0	31	4.5%
New entrants ..	403	3.4	33	3.2%

With regard to the ultimate effects of mass radiography as a preventive measure, they could only hope that if pulmonary tuberculosis in adults was generally due to fresh infection, by means of miniature photo-radiography it would be possible to reduce the risk of fresh infection so that it might soon become a rare event for tuberculous illness to be contracted on the lower deck of H.M. ships.

Surgeon Commander W. G. C. FITZPATRICK added some technical details. The work was done with a specially designed apparatus called the "pulmograph," carrying 35-mm. film. A light-proof tunnel connected the *x*-ray tube, the camera, and a screen on which the image was photographed. The film was exposed on deep inspiration, the exposure varying from

0.3 to 0.6 second according to the man's weight. A device was included for photographing the number of a card identifying the subject. After processing and drying, the film could be viewed by the naked eye, when any gross lesion could be detected, or as a projected image, when lesions were easily seen. About 200 exposures an hour could be made. Any case which showed any abnormality at all was sent for further examination.

Discussion

Surgeon Commander A. R. THOMAS referred to some work already done by various workers in mass radiography. De Abreu in Brazil had examined 14,000 cases, revealing lesions in 3.78%; also 10,000 cases among workers in food trades, revealing lesions in 3.4%. Berner of the German Army had examined 55,000 cases, all of them picked men (storm-troopers), and 1.5% showed tuberculous lesions. Jullien and others in France had examined 145,313 cases, not by photography but by the screen method, and the number of lesions found was only 0.18%. Dr. P. ELLMAN said that this was a unique method for the preventive medicine of the future. There was no doubt that when a patient with pulmonary tuberculosis was sent to a chest clinic with symptoms he was very likely (in 75% of cases) to have comparatively advanced tuberculosis. The problem was to deal with the asymptomatic case. Dr. W. M. CROFTON said that the figures given for incidence in the Navy were evidently reliable, but they ought not to be compared with the figures for the civilian population, which were unreliable. He had never understood why the subcutaneous tuberculin test had been given up. It was not a question of lighting up a dead lesion but of producing a condition of immunization.

Sir WILSON JAMESON said that one of the problems that must inevitably trouble them at the present time was the likelihood of the same unfortunate incidence of pulmonary tuberculosis in young adult females as occurred in the last war. The only thing that could be done was to endeavour to use some better method of diagnosis. The difficulty of using a method of this kind in relation to industry was that if large numbers of people in industry were examined and a certain number of them were found to be infected they must be stopped from working, whereupon their wages would cease and they would go on sickness benefit. This would happen to a great many people who were at present continuing in industry with their incipient tuberculosis. Nevertheless, this sort of examination was being carried out in a limited way in industry with the consent of employers and staffs. He understood that in the United States a camera of somewhat larger size was being used. That this method of examination should be introduced and pushed to the utmost he had no doubt at all.

Questions on the technique of the apparatus were asked by Dr. COCHRANE SHANKS and Dr. CRANCH, and Dr. R. CRUICKSHANK raised the question whether infected dust was not a greater danger than droplet infection in spreading tuberculosis on board ship or in confined spaces.

Surgeon Rear-Admiral DUDLEY said that, while such methods as these were by no means ideal, when it was a question of dealing with large numbers of men speed was essential. He did not agree with some complaint which had been made against the other Services on the ground that they were not trying the procedure. The method was on trial in the Navy; not all the people in the Navy were as yet going through this examination; and the Navy was the first in the field because the tuberculosis problem was much more a naval than an Army or Air Force problem.

SOME PROBLEMS IN ORTHOPAEDICS

The postponed 1940 annual meeting of the British Orthopaedic Association took place at Oxford on January 3, under the presidency of Prof. T. P. MCMURRAY. The meeting, which was well attended, was devoted to the presentation of short papers.

Fractured Neck of Femur, Late Results.—Mr. A. L. EYRE-BROOK and Mr. K. H. PRIDIE (Bristol) said that forty-seven patients out of a total of seventy-five treated by manipulative reduction and the insertion of a Smith-Petersen nail (Hey Groves technique) had been reviewed by clinical and x-ray examination at least one year after the procedure. Bony union was proven in 58% of patients, and in the whole series of seventy-five there had been a mortality of 5.3%. Aseptic necrosis of the capital fragment had occurred more frequently in patients under 30 years of age. The importance of the fracture-shaft angle of Pauwels was emphasized; if this angle was low (below 30°), the results from nailing alone were poor; a fibular graft should be inserted as well.

Excision of the Patella.—Mr. NORMAN ROBERTS (Liverpool) based his communication on twenty patients in whom the patella had been excised. He discussed the uses of the patella and emphasized the following points: (1) Recovery of function after excision is not so rapid as is often thought, though it is more rapid than after suture of the patella. (2) After excision, flexion movement is usually full or is possible at least to the right-angle; there is often a limitation of full extension and the quadriceps is often weaker than normal. (3) Excision is advisable in all comminuted fractures in both young and old patients, and in transverse fractures in middle-aged and old patients. (4) Transverse fractures in young patients should be sutured. If the fragments are markedly unequal in size it is easier to excise the smaller fragment and to suture the rectus or patellar tendon efficiently to the larger fragment. (5) Derangement of the knee due to recurrent dislocation of the patella cannot usually be cured by excision of the patella. (6) Good results sometimes, but not always, follow excision in osteo-arthritis of the knee, particularly if the arthritic changes are mainly in the patello-femoral compartment of the joint.

Correction of Scoliosis.—Mr. G. E. THOMAS (Liverpool) observed that in sixteen patients correction of the deformity had been achieved in the majority by recumbency on a Thomas frame with longitudinal traction and counter-traction applied via the head and legs and "three-point" pressure on the apex of the convexity and the extremities of the concavity. To exert lateral pressure special pads operated slowly by a screw mechanism of the Thomas wrench type were employed. Failure to achieve correction had occurred in very high and very low curves, in severe long-established curves, and in those cases in which there was gross rotation out of all proportion to the lateral curvature.

Fractures of External Tuberosity of Tibia.—Mr. W. S. DIGGLE (Liverpool) reviewed a personal series of these difficult fractures. For those cases in which there was gross comminution and depression of the fragments he had found open operation, replacement of the fragments, and screw fixation the most effective treatment. Most of his patients treated in this way had been able to return to work in about six months.

Compound Fractures of the Leg.—Mr. G. K. MCKEE (Norwich) advocated fixed skeletal traction on a Thomas splint for both tibial and femoral fractures, simple and compound. For tibial fractures a Steinman pin was inserted transversely through the upper tibial fragment and through the os calcis or the lower fragment. The pins were fixed firmly, after reduction by manual traction, to the lateral bars of the Thomas splint by a special clamping device. For fractures of the femoral shaft one pin below the fracture, fixed in a similar way to the Thomas splint, was employed. To avoid undue pressure on the ischial tuberosity or groin the splint was tied to the end of the bed, which was then elevated.

Keinboch's Disease.—Mr. F. C. DWYER (Liverpool) considered that this peculiar affection of the carpal semilunar was probably due to a fibrosis, resulting usually from trauma, of the dorsal ligaments attached to the bone. From an experience of thirty-four patients, in ten of whom the damaged semilunar had been removed, Mr. Dwyer felt that conservative treatment offered the optimum results in a condition which in any event always resulted in a permanently damaged wrist.

Nerve Regeneration and Nerve Grafting.—Mr. J. L. YOUNG, M.A. (Oxford), outlined the preliminary results of experimental work now in progress at the University of Oxford on nerve regeneration and nerve grafting in rabbits. At the start he warned against too closely applying experimental findings to man, even though they had been very accurately demon-

strated in animals. The need for a qualitative method of comparison between different procedures for nerve repair was emphasized. The rate of growth of new fibres was adopted as a criterion and a method of estimating it developed. The rate for rabbits was found to be about 4 mm. a day, was the same in all nerves, and was approximately the same at all levels. Certain suture material occasioned severe reactions—for example, catgut and pigmented silk. White silk, woman's hair sutures, and fibrin "glue" produced the least reaction. Return of function was often rapid, and it was stressed that such rapid recoveries took place after full Wallerian degeneration—they were not due to "physiological interruptions" such as could happen after ischaemia but which cleared up even more rapidly.

Mr. Young pointed out that between interruption and recovery of a nerve's conduction there was delay at three points: (1) In the junction scar—probably about twenty days in man. (2) In the nerve itself during the growth of fibres down it. This was probably at the rate of 2.5 mm. a day in man. These two phases comprised the anatomical delay. (3) In the muscle—the functional delay—about forty to sixty days in man. The delay in the muscle seemed to be shorter if the muscle had been denervated for only a short time—a finding strongly in favour of early suture.

The problems of bridging gaps were discussed. It had been demonstrated that nerves could not be stretched suddenly more than 10% of their total length, and that increase in length from gradual stretching was probably due to actual growth in length of the nerve rather than to stretching. For grafting, autografts had given most success in rabbits, and there were some encouraging results from homografts.

SOME POINTS IN TRANSFUSION

At a meeting of the Shaftesbury Military Hospital Medical Society on February 18 Colonel L. E. H. WHITBY, in a paper on transfusion for war conditions, said that the modern employment of large infusions had rendered gum-saline and haemoglobin-Ringer solutions less generally useful, as in large amounts the former impaired the oxygen-carrying power of the red cells, and the latter might be dangerous unless the urine was kept alkaline. An objection to the use of serum was that it could not be freed from agglutinins and might cause reactions if given in large amounts. Citrated whole blood and pooled agglutinin-free plasma were the fluids adopted for general use by the Army, and would meet all requirements if employed with due regard to the physiological principles involved. In the case of air-raid casualties who had been quickly removed to hospital, post-haemorrhagic physiological changes were minimal: there was no dilution of the blood, the haemoglobin percentage was normal, and there was no secondary shock. In these cases plasma alone was required. Soldiers evacuated from a battlefield, however, would not have been in a position to receive treatment until blood dilution had occurred, and here the indication was for transfusion of blood, both to restore oxygen-carrying power and to combat shock; saline infusion in addition was most valuable for overcoming the tissue dehydration which these delayed casualties suffered, in that haemodilution took place at the expense of tissue fluid. In both cases the subjects contrasted with those commonly requiring transfusion in peacetime practice in that they had been previously healthy and had no cardiac disability; it was therefore safe to give at least two pints of blood or plasma quickly to anyone with a blood pressure consistently below 100 mm. Hg, and then to continue a slower drip-transfusion before, during, and after any operative treatment. If blood derivatives were being used, it was wise to give one pint of whole blood for every three pints of these.

The Trustees of the Bernhard Baron Decd. Charities Fund have sent the final instalment of £2,000 towards the promised £10,000 for a new maternity wing at the Royal Northern Hospital, Holloway. The projected building has had to be postponed until after the war.

Correspondence

Delay in Treatment of Air-raid Casualties

SIR,—I hope your post will bring you many more letters in support of Mr. Norman White's view (March 22, p. 459) that there is unnecessary delay in the treatment of air-raid casualties in London due to the present policy of sending all the casualties from a major incident to one hospital. Hospital authorities have shown some diffidence in referring this problem to their Sector Officers, and have indeed on more than one occasion recorded with pride that after a night raid they had operated till late the next day, while the staff of another hospital less than half a mile away had stood by doing nothing.

It is to be hoped that the Central Medical War Committee will bring strong pressure to bear on the responsible authorities to rectify this failing in an otherwise excellent medical service. The solution would appear to be a simple one—namely, that under present conditions no more than two ambulances should proceed from the site of an incident to any one hospital.—I am, etc.,

London, W.11, March 22. H. STEPHEN PASMORE.

SIR,—Mr. Norman White has raised an important point in your columns. He has shown that in London all the air-raid casualties from one "incident" may be taken to the nearest hospital, no doubt in a praiseworthy effort to obtain the quickest treatment, whereas another hospital at no great distance away may have no casualties at all. Thus there is delay in actual treatment. The same is the case on Merseyside. It has happened that hospitals in one district, sometimes actually damaged by bombing, have had more casualties than could be dealt with, while other hospitals in the same area, easily accessible by ambulance within a short time, quite undamaged and with an enthusiastic staff ready, have received not a single casualty from the whole raid. Experience has shown that many of these casualties require laborious and time-consuming treatment, and that, indeed, one case may require the work of a whole team. Such treatment cannot adequately be given when there is a great rush of cases, and may become impossible if supplies of water or electricity or the black-out become interfered with by enemy action.

Although the importance of early treatment, first shown in Spain, is now generally realized, it would seem that excessive regionalization in the disposal of cases is defeating its own object, and the magnificent work of all those A.R.P. workers and ambulance drivers who strive so much to bring patients to treatment at the earliest possible moment is being made of no avail by the delay that must occur in hospital with the present arrangements.—I am, etc.,

Liverpool, March 30. BRYAN WILLIAMS.

*** The distribution of air-raid casualties is discussed in an article by a special correspondent at page 526 and in a leading article at page 518.—ED., *B.M.J.*

Dyspepsia in the Army

SIR,—Most of the articles which have appeared in the *Journal* on chronic dyspepsia in the Army have been concerned primarily with the incidence of intrinsic organic lesions of the stomach and duodenum in men who have reported ill with "stomach trouble." Payne and Newman (*Journal*, 1940, 2, 819) point out that during the period between the dispatch of the B.E.F. and April 29, 1940, 12.5% of all cases evacuated to the United Kingdom had a primary diagnosis of gastric or duodenal disease. The great majority of these men were shown on radiological investigation to be suffering from chronic duodenal ulcer. Morris (*Journal*, 1940, 1, 1008) recorded the radiological findings in a series of 500 soldiers examined at a military hospital since September, 1939. In about 50% there was positive *x*-ray evidence of chronic gastric or duodenal ulcer. During the last year 256 soldiers have been referred to a general hospital on account of dyspeptic symptoms; these all had a barium meal *x*-ray examination, and the findings were as follows: gastric ulcer, 15 (5.8%); duodenal ulcer, 128

(50%); no ulcer discovered in the stomach or duodenum, 113. In other words, in this small series over half the cases were shown to be suffering from chronic peptic ulceration, and these figures run parallel with those recently published by Morris.

It may be stated, therefore, that if all the chronic dyspeptics in the Army who are referred to large general hospitals were examined radiologically it would be found that destructive lesions of the stomach and duodenum were present in fully half of the cases. Under existing circumstances, however, the true incidence of chronic ulcer of the stomach and duodenum will never be accurately assessed, because there are still a host of officers and men in the fighting Forces—a number of them holding key positions—who, although suffering from these conditions, prefer to treat themselves rather than report their condition to their medical officer. They know full well that if on x-ray examination a gastric or duodenal ulcer is discovered they will be invalided out of the Army without further ado. Those men, therefore, who wish to continue their services with the Forces (and I hold that the proportion of such men is high) find themselves with only two alternatives: either they must report themselves to the medical officer and risk discharge from the Army or they must refrain from reporting their condition and must take a chance on the subsequent development of complications.

It is claimed that as the majority of the men proved to be suffering from these lesions have already been dismissed from the Forces, chronic gastric and duodenal ulcers are no longer a problem in the Army. This, however, is incorrect. The incidence of chronic peptic ulcer among the adult population in Great Britain at the present time is about 12% to 15%, and there is no reason why this incidence should not be approximately the same among those serving in the Forces. If it is conceded that this estimate of the incidence is accurate, chronic ulcer of the stomach and duodenum will continue to be a very serious problem, which will, sooner or later, have to be faced and faced boldly.

I submit that those who are shown to be suffering from chronic peptic ulcer and who wish to be invalided out of the Services should be accorded this opportunity, as such subjects are unlikely to prove co-operative whatever line of treatment is adopted. But those similarly affected who, on the other hand, wish to continue to serve with the Forces should be given every facility for being treated in specially staffed and well-equipped hospitals set aside exclusively for the management of these cases. If carefully supervised medical therapy were applied thoroughly and efficiently in such specialized hospitals a large number of these soldiers could be rendered symptom-free and fit for further service; and the majority with chronic callous lesions or complications which demand operative treatment could, following such surgical measures, be placed in a graded position for a probationary period, and those proving to be satisfactorily cured be returned in due course to their units.—I am, etc.,

London, W.1, March 21. RODNEY MAINGOT, F.R.C.S.

Crush Injuries

SIR,—The articles on "Crush Injuries" in the *Journal* of March 22 are of intense medical interest, especially as further investigation of such accidents might result in combating successfully the syndrome referred to and therefore in saving lives.

A large proportion of the fatal accidents in mines result from crush injuries, many of them similar to those which are brought about by air raids. The experience and views of surgeons who deal with a large number of such cases in coal-mining areas would therefore be of immense value and greatly appreciated.—I am, etc.,

S. W. FISHER,
March 31. H.M. Medical Inspector of Mines.

SIR,—It may seem an impertinence for one with no experience of these injuries to write, but on reading the articles in the *Journal* of March 22 I felt that some ideas might justifiably be put forward.

During the time—a few hours or maybe days—that a person is buried under fallen masonry there is a continual loss of body fluid. There is the loss of intake fluid that the person would have taken during that period, and there is the loss that goes on ceaselessly during breathing. As this loss goes on the blood fluid must decrease and therefore the blood salts become more concentrated. The case becomes one of lowered blood volume and a resulting diminished renal blood flow. The *Journal* states, "Attempts made to explain the rising blood urea of hypochloraemia, gastro-intestinal bleeding, Addison's disease, diabetic acidosis have usually invoked the idea of lowered blood volume and diminished renal blood flow." Again, it states that "these cases resemble the toxaemia of severe burns"; but the ill-effects of a burn are in direct proportion to the loss of fluid from the body due to the burn: so again the condition is due to the loss of body fluid.

In crush injuries we have not only a loss of fluid but also the effects of pressure. This pressure forces the blood from the part, and incidentally helps to prevent collapse by sending the blood to the brain, heart, and lungs. Where there has been a great loss of blood we bandage the limbs to force the blood to these parts. In crush injuries the weight does this.

To prevent caisson disease the chief treatment is slow decompression. Is it not permissible to take this as an analogy and copy it? When the weight is removed in a case of crush injury there must be a sudden expansion of the limb and a quick suction of blood into the part. This sudden suction must cause numerous slight extravasations of blood, and the sharp withdrawal of blood from the brain must lead to collapse. Would it not be better to have slow decompression in these cases? It would not be possible to withdraw the debris slowly, but it would be possible to bandage the part tightly as it becomes exposed. This bandage could then be slowly slackened over a period of time, and during this time fluids could be administered to make up for the fluid loss and to decrease the concentration of the blood.

The *Journal* also stated that "the pathological appearance of the kidney is said to have borne a resemblance to the transfusion kidney." Is it not possible that it *is* a transfusion kidney? In severe bleeding there is a loss of all the constituents of the blood, while in these cases there has been a loss not of all the constituents but only of the fluid part. This may have an effect on the blood transfusion.—I am, etc.,

Stewarton, Ayrshire, March 26. E. R. LLOYD.

SIR,—I have read with interest the accounts of renal failure supervening on crush injuries given in the *Journal* of March 22.

I think possibly toxic substances or toxins from the crushed muscles are absorbed into the blood and act on the kidney tubules as poisons. First the renal system is thrown out of gear, then secondary effects are observed in the blood and on other systems (e.g., lungs and heart). I think plenty of glucose would neutralize these toxins. I had once a very bad case of burns to treat—a child under 2 years with a large area of body surface burnt. Supposing that toxins must be absorbed from this large surface, I gave her as much glucose fluid as she would take—indeed, pushed it. (The burn was dressed with silver nitrate and tannic acid.) The child got jaundice and later nephritis, but was still given as much glucose as possible and recovered.

I do think that glucose somehow or other neutralizes toxins which may for the time being prove too much for the kidneys. Anyway, I think it is worth trying—both in drinks and in light diet; it should be pushed in as large quantities as the patient can be persuaded to take.—I am, etc.,

Liverpool, March 27. FLORENCE M. E. DAVIES.

Cerebral Venous Thrombosis after Childbirth

SIR,—The speculation conveyed in Dr. J. Shafar's letter (March 22, p. 455) has been in my mind also since I read the annotation on Batson's work (*Ann. Surg.*, 1940, **112**, 138) in the *Journal* of February 22 (p. 284). The paper by Dr. Sheehan and myself (March 8, p. 349) had been submitted for publication some time before the annotation appeared, and we were not aware of Batson's article, but in connexion with certain cases of thrombosis in the superior longitudinal sinus following childbirth, which I hope to report soon, the question had been persistently in my mind whether the thrombus in the sinus could not be in some way metastatic. When I read of Batson's findings I realized that it could. It is most tempting

to suppose that a minute fragment of clot, carried up through the vertebral system of veins, might lodge in an irregularity of the wall of the sagittal sinus and form the nucleus of a new clot, but I do not know yet whether the pathologists will support this theory; in Case II of our paper no such nucleus was found in what appeared to be the primary clot. If the fragment found its way into a superior cerebral vein it might conceivably act as an embolus, but it seems more likely that a secondary clot would have to be deposited on it before blockage occurred; that, however, is a minor point. I may say that one of my cases of sinus thrombosis lends further support to the theory of metastasis via the retrothecal veins, because the patient developed a spinal lesion as well; but, on the other hand, it must be admitted that the rarity of spinal lesions provides an argument against the theory.—I am, etc.,

London, W.1, March 27. J. PURDON MARTIN.

The New Price of Insulin Preparations

SIR,—You were good enough to publish recently a plea for the use of the stronger solutions of insulin (*40 and 80 units c.cm.*) instead of 20 units on the ground of *national* economy—fewer bottles needed, less packing, less labour. Now the price of insulin has, I suppose inevitably, been raised to cover increased costs, and the argument of *personal* economy has been added. The following figures show that the retail increase is much greater in the weakest solution of insulin, and that the increased price can be largely offset by changing to more concentrated insulins.

Strength	Cost per 100 Units of Soluble Insulin	
	Old Price	New Price
	s. d.	s. d.
20 units/c.cm.	1 0	1 5
40 units/c.cm.	11½	1 3
80 units/c.cm.	11	1 0½

It is clear that the increase in price can be largely avoided by using the stronger concentrations. The clinical effect is the same with all strengths, but may I emphasize the bulk of the injection must be *halved* or *quartered* to correspond to the stronger concentrations—otherwise hypoglycaemic disaster.—I am, etc.,

London, W.1, March 27. R. D. LAWRENCE.

Continuous Pentothal Anaesthesia

SIR,—Dr. Hastings Moore's description of the complications of pentothal anaesthesia (March 22, p. 462) suggests that his patients either do not receive premedication or receive preoperative atropine.

1. *Fibrillation of Muscles.*—Common with evipan and rare with pentothal, especially so after morphine.

2. *Sudden Muscular Contraction.*—Always due to too light anaesthesia and occurs less frequently with growing experience. The arm should always be so fixed as to prevent flexion of the elbow.

3. *Very Shallow Breathing.*—Should never be accompanied by cyanosis if the airway is clear. Continuous pentothal should not be employed by those inexperienced in its technique except in the presence of someone who is so experienced.

4. *Persistent Coughing.*—Commonest in patients who have not received premedication, and frequently initiated by an artificial airway. The orthodox view[1] is that further injection should be withheld, the cough and subsequent laryngeal spasm being due to a stimulant effect of the barbiturate on the parasympathetic nervous system.[2] It is exceedingly dangerous to increase the dosage as the respiratory centre is further depressed and the tendency to laryngeal spasm increased. Coughing will cease spontaneously, but may be cured by intravenous injection of 5 c.cm. of coramine or 2 c.cm. of cardiazol. Cyanosis with laryngeal spasm calls for most urgent remedying.

5. Doses of 2 grammes of pentothal are excessive. Prolonged post-operative sleep, with its attendant complications, led to the abandonment of the older barbiturates as anaesthetics.[3] Although pentothal is clinically innocuous, severe liver damage has been reported in experimental animals,[4] and Maclagan's results[5] suggested a mild degree after anaesthesia in human beings. In view of this it seems imprudent, except in emergency, greatly to exceed the dose of 1 gramme recommended by the makers. Pentothal can satisfactorily be followed or supplemented by nitrous oxide,[6] and the dose is reduced by at least one-third after morphine. It would be regrettable if one of the most valuable drugs available to us were to fall into disrepute as a result of its misuse. An artificial airway should not be necessary on leaving the theatre and, if used, should be lubricated with vaseline containing percaine or decicaine to dull the local reflexes.

Post-operative restlessness has not been found in some thousands of cases where morphine had been used beforehand, and would be more likely to follow large than small doses.[6] A thrombosed vein, without symptoms, was found in my arm one week after intravenous pentothal. In view of this Dr. J. B. Wyman has undertaken a most painstaking research into its *frequency and causation, preliminary reports from which* suggest an incidence as high as 25%. The fundamental point is that continuous pentothal anaesthesia is entirely safe only in the absence of cyanosis. Anything else is of minor importance.—I am, etc.,

Calcium Requirement

SIR,—Possibly you will be good enough to allow me to rectify a misunderstanding. "Children and pregnant women require other items of food as well as calcium which can only be supplied by milk. The latter cannot be replaced by bread calcium." They require first-class protein, for instance, and other items as well. Since milk must be given in any case to children and pregnant women for the sake of the many items of food they require, they are bound to get the necessary quota of calcium. Moreover, the work of Meulengracht (Meulengracht, E., and Meyer, A. R., *Acta med. scand.*, 1937, **92**, 584) suggests that where calcium deficiency is a factor the condition cannot be regarded as a single deficiency but a combination, and they had to treat those cases with vitamin D as well as with calcium. This suggests that bread calcium would not help this type of case.

You say there is no proof at all that "a large number of middle-aged people who exhibit evidence of kidney damage, etc., would suffer injury from this extra chalk." That a large number of middle-aged people do exhibit evidence of incapacity of normal renal concentration is a fact in support of which many of your readers will bear me out. Polyuria, and particularly nocturia, is a manifestation of defective renal concentration. If we include border-line cases who later develop more pronounced signs the number is very large indeed. I have been working for a good many years on this problem. It will be seen from our monograph *High Blood Pressure* that under certain conditions when the calcium intake is increased the work of the kidney due to calcium excretion may approach urea excretion values. It must be borne in mind that a slight increase in calcium intake may cause a considerable rise in the kidney work. But apart from kidney work it is an established fact referred to in our paper that calcium interferes with renal function. To increase the load on the kidney in such cases is as rational as to make a heart-failure case climb Snowdon. We must bear in mind that there will be the cumulative effects of calcium intake extending over a number of years. I say with the same certainty as that two and two make four that large numbers of middle-aged people would suffer injury if calcium were added to bread.

Finally, I would like to make the following point. The evidence, such as it is, which might justify the Government proposals is based on pre-war conditions. You do not accept this evidence, for you do not recommend the perpetuation of the "reform" after the war. I am not aware that there has

been an exhaustive inquiry with regard to the calcium problem under present conditions. Your leader, therefore, is merely an expression of opinion. This is not sufficient to justify such a drastic measure. Our paper was concerned solely with the scientific side of the problem. Clearly if you believed that the "reform" is scientifically sound you would not advocate its discontinuation after the war. I am glad that on the broad issue there is agreement between us.—I am, etc.,

Liverpool, March 22. I. HARRIS.

Calcium and Arteriosclerosis

SIR,—I have read Dr. Harris's letter on calcium and arteriosclerosis (March 22, p. 460) and also your editorial comment, and it appears to me that the politically supported therapy of communal dosage with calcium is just as "shot-gun" as Dr. Harris's communal deprivation of calcium. In both cases some people will benefit and others suffer, and the precise ratios of these are inevitably unobtainable. My own preference is towards the ideas of Dr. Harris, which are at least less expensive, less artificial, and more rational.

From the theoretical point of view, it seems to me that the quandary arises not so much from the "unprovability" of the ultimate analysis of the variations in the human blood as from the *static* concept of pathological processes which is still in the minds of many medical scientists. Thus, a man of 55 walks into the surgery and his condition is diagnosed as arteriosclerosis or other cardiovascular degeneration, and it is presumed that this condition is new or at least of a few years' duration. It is my belief that the seeds of arteriosclerosis, etc., are sown in the first five years of life in a soil that is present even before that early age. The *dynamic* concept of pathology postulates that "the child's diet is father to the man's arteries," and this should serve to direct the attention of calcium research workers towards the investigation of the blood of children and young people. The amassing of vast accumulations of research data, which must sooner or later reach the dustbin, seems to me regrettable when there are so many fruitful fields for research brains. The rationale of calcium therapy involves the important question of the reversibility of pathological cellular reactions and processes, and while I believe this reversibility is possible in early life, and in some cases of adult life, I think that such reversibility must disappear with age.

The lesson is clear: we cannot undo arteriosclerosis (just as we cannot surround every brick in an old slum dwelling with new mortar and cement), but we can prevent arteriosclerosis by diverting scientific, aesthetic, sociological, and political attention to those potential arteriosclerotics of to-morrow—the children of to-day. Until then, the human "slum dwellings" must be buttressed as patiently as possible. In general practice, the problem is patience, not patients, and in any case "the treatment of arteriosclerosis is a regimen, not a drug."—I am, etc.,

Kearsley, Lancs, March 22. D. OCKMAN.

Medical Planning Commission

SIR,—I have read with much interest the correspondence on the Medical Planning Commission which has been appearing in the *Journal* for several weeks. I feel that the B.M.A. is to be congratulated on having set up such a Commission and not waited for the Government to force its own plans on us, maintaining that we have no plans of our own. The medical services, including the general practitioner service, call for better organization; why not plan this ourselves?

For a time correspondents seemed almost entirely concerned with the constitution of the Commission—whether a sufficiency of general practitioners, of young men, of women had been selected to serve. While feeling that all these groups should be represented, the proportions seem to be of minor importance. Frankly, I consider the proportion of able men is greater in the ranks of the consultants than in those of the general practitioner, while conceding that the most brilliant man or woman may be found in the latter. But what we need is people of the reforming spirit, with knowledge and reasonable respect for the past. The reforming spirit may burn more fiercely in the elderly than in the young, and I have found junior colleagues with over-much respect for past traditions.

But lately a change has come over the correspondence, and writers, eschewing criticism of the composition of the Commission, are coming forward with suggestions for the Commission to consider—surely a more fruitful course to take. No better suggestion has appeared than that put forward under the title "Give Us the Tools," by Dr. Montuschi (March 22, p. 458). There should be no difference of opinion about the necessity for providing the general practitioner with proper tools, the means of investigating his patients thoroughly—means possessed at present only by the hospital staffs,—without which he cannot—*pace* Dr. Montuschi—even diagnose anaemia. But Lord Dawson of Penn, in his Cavendish Lecture in 1919, put forward a scheme providing everything Dr. Montuschi wants, yet little in the intervening years has been done to put this scheme into operation, and I conclude from the absence of any support from him, when I have on various occasions attempted to awaken interest in the scheme, that even its author has lost heart. Is not this because we have been over-much engaged in consideration of remuneration to the disadvantage of service?

I am convinced the reorganization of the medical services on the lines advocated by Lord Dawson would be a great advance from the conditions now prevailing, and would restore to us the public respect, which I fear we have been losing.—I am, etc.,

London, W.8, March 25. HAROLD H. SANGUINETTI.

SIR,—Much has been written since the details of the Medical Planning Commission came out, the objects of which are to study wartime developments in relation to the medical services of the country. The sum and substance of all this correspondence is that there is widespread dissatisfaction with the representatives elected to serve on this Commission. To boil down the facts to a minimum: What is the question that is troubling every medical man—whether in the Services or not—to-day? Is it not, Are we or are we not going to have a State Medical Service after this war is over? If we are going to have a State Medical Service, then there are two sides from which we must view the question: (1) the outlook and views of the medical profession on the subject; (2) the equally important observations of the general public.

If we consider the first of these, let us here and now admit that the B.M.A. does not represent the whole of the medical profession. Much as that is to be deplored it is nevertheless the truth. Therefore, if the B.M.A. desires the thorough backing of the medical profession it would be well if it were to try to find out the views of every member of the profession, whether in the B.M.A. or outside it. Surely it would be worth sending out to each medical man a simple questionary, sounding his views on this most vital problem.

Second, and probably even more important, would it not be a good plan to try to find out just what the patients might think of it all? After all, they would probably be even more affected than we would by the change. A simple, plainly worded circular stating the changes that would take place and how they would affect the patient and his relations with his doctor could quite easily be devised. Each medical man could be supplied with a quantity of these circulars enclosed in stamped addressed envelopes. These could be distributed to his patients as they attend at the surgery, and their co-operation in answering them could be solicited. From both sides this would yield valuable information, and would be a good foundation on which to build up future plans. Then there could not be any grumbling that every effort had not been made to try to get the real opinion of all concerned in the matter.

In general it will be admitted that the younger generation lean towards a State Medical Service, while the older practitioner is much more sceptical of this change. I agree with Dr. Illingworth in his letter (March 8, p. 381) that hospitals could be run on a much better system. It is ridiculous that some hospitals should always be crying out for funds while others have plenty and to spare. It is the average man in the street, who gives least towards the hospitals, who requires their services most, so why should they not be financed and run by State funds? Better pay, too, for house-surgeons and members of the nursing profession is indicated. Just because the volun-

tary hospitals think that a doctor is only gaining experience they put him off with a trivial salary, regardless of the fact that he has still the responsibility to shoulder. Again, after this war is over the voluntary hospitals will not be able to depend on big individual donations, as there simply won't be the money about. I think, too, that hospitals should have full-time surgeons attached to them, who would be paid an adequate salary for the work they do in the hospitals and who would not be dependent for what they earn on their private outside work.

When it comes, however, to roping in the average general practitioner as a State servant I am not so sure that this move would be for the good either of the profession or of the public. For the profession it would make the science of medicine very much in the nature of a job to be done regardless of any personal feelings, and individual initiative would be very liable to suffer. For the public it certainly would disturb that essential personal element which is so bound up in the work of a general practitioner. No doctor who has been in general practice for any length of time will deny that the best practitioner is often not so much the one who knows all about the most obscure diseases as the one who has the personality to get the confidence and trust of his patients. I am sure it is on this point that the general public will have much to say.

I do not say that the panel system is a good one or that an extension of it is much to be desired. It is the best of a bad system, and actually in the more rural districts and smaller towns it works quite well, where the doctor has the time to treat his panel patients just as he does his private ones. It is in the large industrial centres that the panel system falls down, and patients are treated not so much as human beings but as so many nonentities who have to be pushed out of the surgery in double-quick time, simply because the doctor has not the time to devote to the work. Was this system accepted *en bloc* by the medical profession as a united body? The answer is very much in the negative, and yet here we have been, for the past thirty years, labouring along enduring a system which was none of our making. And is not this going to happen again unless the profession gets together and the consensus of opinion is found? If a State Medical Service is imposed and it does not work out as its advocates thought it would, what good will it be twenty years hereafter to say that it was not of our making?

I think this is an excellent opportunity for the B.M.A. to gain the support of the whole of the profession by finding out the opinions of each individual member and using this as a basis for future developments rather than trusting to the conclusions which a Medical Planning Commission may come to. It certainly would be the more democratic way.—I am, etc.,

J. M. MUIR, M.B.

Thongsbridge, nr. Huddersfield, March 19.

SIR,—Dr. Alfred Cox (March 15, p. 419) makes the astounding statement that "young doctors, unless they are predestined medical politicians, are usually too busy making their careers to take much interest in medical affairs." This strikes me as a typical example of the official or "headquarters" mind. It would be a bad day for England if only those who were predestined politicians or belonged to the select company at Westminster were capable of legislating for the future, and it will be an equally bad day for the medical profession when its future is entrusted entirely to those who have held high position in various departments or found favour at headquarters. The younger doctors are interested, vitally interested, in medical affairs, but it does not follow that they are always able or free to voice their opinions at B.M.A. meetings.

As a member for many years and an office bearer, I am becoming more and more impressed by the number of worthy men with ideas who are outside the ranks of the B.M.A., who sooner or later will become an "official" opposition as mentioned by Dr. W. Lyle (p. 420). And they are outside not because they are uninterested in medical affairs, but because they have in the past come up against the official type of mind which sees little wisdom in youth and now considers that the members of the Medical Planning Commission should be chosen only according to past deeds and past experience. This Commission is to plan for the future, which will mainly concern the young doctors of to-day, and even if at present "they are doing something more urgent and more important" steps could be taken to present their written evidence to the Commission obtained from many quarters.

The seer foretold that the old men should dream dreams but it was the young men who should see visions. There seems a danger to-day that the old men, who admittedly have the experience of past things, think that this carries with it the ability to see visions for the future. This does not follow. It is surprising how, as we grow older, we lose touch with the thoughts and aspirations of the succeeding generation. I and many of my age are old enough to know something of the difficulties and pitfalls of general practice, but we are also young enough to remould our medical lives on an enlightened plan, and have time in which to carry the plan into action if allowed to do so. The gulf between youth and age is partly due to youth thinking all old folk are out of date, but this attitude has been largely brought about by age seeing all youth as rash, unschooled, and foolhardy, and shutting all but the hoary hairs out of their inner counsels.

If the findings of the Commission are to receive the welcome reception of the profession as a whole and young men in particular, it would be well to see that the gulf between age and youth among its personnel is closed, and that ample inclusion is made of those who have the ideas and the time and vigour to see them carried into effect.—I am, etc.,

London, S.W.17, March 23. E. GERARD HOUSDEN.

SIR,—Dr. Alfred Cox's letter in regard to the Medical Planning Commission (March 15, p. 419) contains the naïve statement that "young doctors . . . are engaged on something even more important and more urgent." Surely the great majority of all active members of the profession are today engaged in the whole-time pursuit of their task to help the community to a successful conclusion of this war. Perhaps Dr. Cox, with tongue in cheek, thinks that that is precisely the fitting circumstance in which to take the profession's name in vain. Will the young men be grateful to the Commission for its haste to arrange the future in their absence? How very satisfying it is for those of us too old to be engaged in "*something more urgent*" that we should occupy ourselves with the *young men's* business!—I am, etc.,

London, S.E.24, March 15. KENNETH MCFADYEAN.

Malignant Measles?

SIR,—In reply to the correspondence on Dr. Audrey Baker's possible case of malignant measles (March 8, p. 380), I would like to mention a similar case I saw in January, 1940.

A boy aged 3½ years was admitted to hospital on January 17. He had a copious nasal discharge, loose cough, slight photophobia, and a temperature of 99.6°. On January 20 he developed a typical measles rash, and inquiry at the hospital from which he had been transferred revealed that several cases of measles had developed in the ward he left on January 17. On January 21 a severe purpuric rash appeared in the napkin area. The purpuric spots were thickly distributed and by the evening they formed solid blue-black ecchymoses on the buttocks and thighs. Small discrete purpuric spots became generalized over the whole body and on the uvula and fauces. The child's condition deteriorated rapidly, he looked extremely toxic and pale, the pulse was impalpable, and the heart rate rose to 160. Finally signs of bronchopneumonia developed at the right base, and the child died at 11 a.m. on January 23.

The chief findings at the post-mortem examination were a terminal bronchopneumonia and signs of extreme toxaemia. There was no haemorrhage into the suprarenals, but there was a considerable area of haemorrhage in the tissues round the lower pole of the right kidney.

I diagnosed this case as malignant measles.—I am, etc.,

Hereford, March 27. M. E. WARD.

Public Health Service

SIR,—If one may judge by the extensive correspondence you have had on the Medical Planning Commission, there must be something far wrong with the present-day practice of medicine in this country. One writer suggests that we look back and see where we have taken the wrong turning. In my opinion we do not have very far to look; and I think I am confirmed in my view in reading the other day in the *Times Literary Supplement* a review of *Practical Public Health*

Problems, by Sir William Savage, a very distinguished worker in the field of hygiene whose writings must be read with respect. The reviewer states:

> "He speaks of himself as an 'old-timer bred in the old tradition' in spite of 'a prolonged schooling along more modern lines.' Not so long ago the duties of a Medical Officer of Health were confined to matters of preventive medicine and collective hygiene. In the course of the last two decades he has become 'enmeshed—*malgré lui-même*—in institutional provision for the treatment of his failures in preventive medicine. In consequence he tends more and more to take less and less interest in those specialized problems of environmental hygiene which occupied so much of the energies of his predecessors.' The field is thus left to the engineer and the sanitary inspector. Yet the problems raised are not purely engineering but have important health aspects which require the help of the scientifically trained medical expert. In his book Sir William Savage deals with this no-man's land between the functions of the M.O.H. and those of the sanitary inspector and engineer. The appearance and development of such a no-man's land show that unification, no less than co-ordination, has its dangers. Between personal medicine and collective preventive sanitation there is a fairly clear line of demarcation. That the two branches of hygiene should be brought and kept in touch with one another is in the highest degree desirable. Yet there seems to be good practical reason for basic departmentalism."

I think this warning is very much needed at the present time. If we glance at the history of the evolution of the present-day M.O.H. we find that he was originally an expert in sanitation and epidemiology, held in high respect by his colleagues in other branches of medicine. His successors have become regular Pooh-bahs: school medical officers (with no special training—six months house appointment is adequate for officering a post as an assistant school medical officer); chief tuberculosis medical officers (with no training in tuberculosis, but that ignorance covered up by the appointment of a "clinical tuberculosis officer"); chief venereal disease officer (again with a "clinical V.D. officer"), chief of maternity and child welfare clinics (divorced from the actual practice of obstetrics); directors of our hospitals (general, mental, and all the rest); and, last, administrators of our emergency war hospitals. His present state can be summed up as a jack-of-all-trades and master of none.

Now, Sir, are we to hand over the administration of all our professional activities to such an officer? If so, many of us will not regret our retirement. I would suggest that the M.O.H. is not a fit and proper person to be raised to this eminence in the profession. He has neither the training nor the experience nor the necessary professional status. In fact, I question if any medical man has all the necessary qualifications, and I would suggest that the M.O.H. be relegated to his proper sphere as a specialist in collective hygiene, and that his advisory functions to local authorities be handed over to a professional body embracing all branches of the profession practising in the district (medical, surgical, obstetrical, and laboratory). We have the germ of the idea in our Local Medical and Panel Committees.

In overhauling the M.O.H.'s department, attention is required to the various clinics that have grown up with him. Instead of our tuberculosis dispensaries, school, child welfare, and maternity clinics staffed by cheap "specialists," let us have real specialists of consultant status. What practitioner in his senses would send a patient to any of these clinics—with a few notable exceptions—say, when a university-allied hospital was available?

This is too big a question to consider in a letter such as this, but I might add that I have been informed that the abolition of the M.O.H. in his present state has been mooted in higher administrative circles, and also that the redistribution of our administrative areas is considered to be long overdue—that the present artificial county boundaries should be replaced by a regrouping around their natural centres, the cities and towns. Something of this sort is essential before we can get very far with any medical planning.—I am, etc.,

Galashiels, March 18 KENNETH MCLAY, M.D., D.P.H.

Village Settlements for the Tuberculous

SIR,—Dr. T. Francis Jarman writes (March 1, p. 335): "That a nation-wide need exists for workshops and factories where workers with arrested tuberculous lesions can be employed under special conditions and under medical care, no one working in anti-tuberculosis schemes can deny." This I ascertained to be true several years ago from the replies I received from many tuberculosis medical officers and superintendents of sanatoria to a questionary which was published in a report I was asked to make for the former Labour Party Advisory Committee (Public Health).

During the period I was tuberculosis medical officer I was mainly responsible for the foundation and administration of the late Efford Tuberculosis Colony (Plymouth) for ex-Service civilians and pensioners, and experience there taught me that the Government was *not* prepared "deliberately to foster and encourage the initiation of schemes of this kind." There is little reason to believe that the Government will do so *now*. On the contrary, this "colony," under the patronage of Prince George and members of the public health committee (Plymouth), though well situated and housed, received no financial support from the Ministry of Health or borough council, and it had to close down after a struggle for existence for ten or twelve years. It was conducted on the lines of the Papworth Village Settlement, with which and with whose founder I was personally acquainted, and to which I sent many patients. I attribute this failure mainly to the "restrictive influences of the profit system on medical economics" and partly to a belief that it was an "experimental" scheme.

At that time I visited the medical institutions of the U.S.S.R., and I found on inquiry that only "night sanatoria" for the tuberculous were included in their after-care schemes of "labour prophylactoria," and it is good news to hear from Dr. Jarman that the principles and practice of the late Sir Pendrill Varrier-Jones are now included in these schemes within the organization of the medical service of the U.S.S.R. In any case we should all work for a new world order, incomparably superior to the Nazi one, which would include such settlements within a complete, unified, efficient, and non-bureaucratic medical service on a national basis. I may say that the same fate as that of "Efford Colony" befell the "Laira Hostel (Plymouth) for Children" (who were "home contacts" with cases of active tuberculosis) after five years' struggle on a voluntary basis.—I am, etc.,

F. G. BUSHNELL, M.D., D.P.H.,
Vice-President and Life Governor, Devon and Cornwall Sanatorium.

Nurse Anaesthetists

SIR,—It is to be hoped that Mr. Loughnane's experience (March 22, p. 463) regarding anaesthetists' attendance at hospital is unusual; so far as my experience of teaching hospitals is concerned it is not only unusual but unique. If, however, his unhappy lot is a common one among operating surgeons, surely the proper remedy is not nurse anaesthetists but more competent qualified anaesthetists and better arrangements to regulate their attendance.—I am, etc.,

London, W.1, March 24. J. BLOMFIELD.

The March issue of *Industrial Welfare and Personnel Management*, the journal of the Industrial Welfare Society, contains an article on "The Rhythm of Work and Rest" by Dr. W. M. Burbury, who writes: "A great deal has been done recently in providing recreation during the working period, concerts at the lunch break, or music in the workroom. These things are very good in themselves, but they are not necessarily good for all workers. It depends on the type of person. Even in these recreative outlets there must be variety in order to avoid monotony: radio for half an hour, freedom to talk for another half-hour, and different kinds of relaxation from day to day." Dr. Burbury discusses the disturbances in the rhythm of our lives brought about by the war. Another article, on "Industrial Catering in Bombed Areas," records the experiences of a Coventry works canteen. Dr. John P. Steel, medical superintendent of the Smithdown Road Hospital, Liverpool, gives a very favourable account of the use of pure cod-liver oil (which is rich in vitamin A and D content) for the dressing of burns and wounds. He insists that only a medicinal oil should be used, and it should be pure, sweet, and fresh, just as it exists in the liver of the live fish: the word "crude" has led to misunderstanding and disfavour.

Obituary

SIR WILLIAM SMYLY, M.D., F.R.C.P.I., F.R.C.S.I., HON. F.R.C.O.G.

Sir William Smyly was born at 13, Merrion Square, Dublin, on November 14, 1850. He was the third son of Josiah Smyly, M.D., and Ellen his wife, who was the founder of Smyly's Homes and Schools for necessitous children. His elder brother, Sir Philip Smyly, was a celebrated surgeon, who was Surgeon-in-Ordinary to the Queen in Ireland. Smyly married Eleanor Colpoise, younger daughter of Henry Tweedy, M.D., thus increasing his connexion with the medical profession. They had two sons and four daughters: one son died in early life; the other, after a distinguished career at Trinity College, went to China, where he is engaged in medical missionary work. Of the daughters, one married her cousin, Sir Philip Crampton Smyly, late Chief Justice of the Gold Coast; the second married Dr. Hobhouse of London; the others remained unmarried, and were devoted to their father.

Smyly was educated at home and at Trinity College. Later on he studied in the clinics of Vienna and other cities on the Continent. After qualification he decided to specialize in obstetrics and gynaecology, and became assistant master at the Rotunda Hospital. In November, 1889, he became Master of the Rotunda, at a time when the fortunes of the hospital were at rather a low ebb; but soon the tide turned. From the first he showed indomitable energy: there was neither excitement nor fuss about this energy; "the dear little man," as some of his patients called him, pursued his object until it was accomplished. Gynaecological surgery was in its infancy, and he immediately took steps to ensure that the promising infant should be looked after. His first act as Master was to collect funds to build a wing for gynaecological patients. As the result of much enthusiasm on his part and that of his wife in raising money, and through the generosity of friends, the "Cairnes" gynaecological wing was completed, and soon aseptic gynaecological surgery was in full swing at the Rotunda. The theatre was small and, according to modern standards, poorly equipped. It was the first theatre in any obstetrical hospital and was far in advance of its time; an original device in its design was a glass screen *separating the onlookers from the operating* table. Much excellent work was done here when mortality was high elsewhere.

Smyly was an inspiring teacher, and postgraduates from all parts of the world flocked to the hospital. Needless to say, obstetrics was retained as the prime study. I have been able to trace the reports of the Rotunda for four years of his Mastership: his results were good, in spite of the fact that there were ten cases of sepsis in his first year; he overcame this outbreak so well that he had no mortality from this cause in the subsequent two years. His chief method of dealing with the epidemic was *the prevention of vaginal examinations*. I believe he was the first to show the value of morphine in eclampsia. "No meddlesome midwifery" was his watchword; and it is interesting to realize that in the diminutive labour ward, *with its concrete floor*, the results were at least as good as those obtained in the modern labour wards; and it must be remembered there were no gloves, no masks, no shaving, but there was great supervision: and cleanliness and natural labour were the key words. He introduced trained maternity nurses instead of untrained midwives into Ireland. There had been no night nurses, and the midwives used to sleep at night, sometimes in bed with the patients. He used to say: "If you give me a good nurse, I can train her into a good midwife, but I cannot train a midwife into a good nurse." Among other interesting innovations was the introduction of vegetables into the diet of the nursing mother.

When Smyly had completed his period at the Rotunda he became gynaecologist at the Adelaide Hospital, where he was highly successful both as an operator and as a teacher. Personally he was a beloved physician, and had an extensive private practice. He was a first-rate raconteur, and it was a delight to sit next to him at a dinner. His family life was ideal; he was devoutly religious, and served on the committees of many charities devoted to religious objects. He represented the Dublin Diocese of the General Synod of the Church of Ireland, and was associated with numerous nursing societies, Boys' Brigade, etc. The Masonic Order has lost in him a valuable Brother. For many years he was the Senior Grand Warden in the Grand Lodge of Ireland. In his youth he was a violinist and played a good deal of chamber music.

He contributed largely to obstetrical and gynaecological literature, and attended the Royal Academy of Medicine until comparatively recently. He had many honours conferred on him. He received his Knighthood in 1905. He was a past President of the Royal College of Physicians in Ireland; of the obstetrical section of the Royal Society of Medicine; of the Royal Academy of Medicine in Ireland; and of the British Medical Association. He received the Honorary Fellowship of many colleges and learned societies, including the Royal College of Obstetricians and Gynaecologists, the Royal Academy of Medicine in Ireland, the Edinburgh and Leipzig Obstetrical Societies.

Although he had attained the great age of 90, we saw him until quite recently at the reunions at the Rotunda and at the Royal College of Physicians, where he was still his cheery smiling self. Sir William Smyly was an example to the young and to the old; a pleasant companion; an honest and knowledgeable physician always more than alive to the necessity for the observation of strict ethics. He lived his span and lived it well. We extend our sympathy to his family, who, like ourselves, will surely miss him.

B. S.

W. D. DONNAN, M.D.

We regret to announce the death on March 17 of Dr. William Dunlop Donnan of Holywood in his seventy-second year. The son of William Donnan of Holywood, Co. Down, he was born in Colombo while his parents were in Ceylon. He was one of a distinguished family, and his younger brother, Prof. F. G. Donnan, was the pupil and successor of Sir William Ramsay at University College, London. Dr. Donnan was educated at Queen's College, Belfast, and graduated in the Royal University of Ireland in 1893. In 1898 he was awarded the much-coveted gold medal of the Royal University when he obtained his M.D. He was a lifelong member of the British Medical Association and a Fellow and past-president of the Ulster Medical Society.

Donnan began practice in Holywood more than fifty years ago. There he became medical officer of Castlereagh No. 2 Dispensary, A.R.P. medical officer for Holywood, and police surgeon. The writer of this memoir has many happy recollections of his residence in the old Royal Victoria Hospital at the time when Dr. Donnan was house-physician and house-surgeon. He owes much to his friendship and to his early instruction in clinical medicine. During Donnan's first years in practice he was an ardent laboratory worker, and from Lorrain Smith's laboratory he and the late Dr. James Colville published in the *British Medical Journal* in 1898 the first paper from Ulster on the Widal reaction. He maintained his interest in this type of work, as some of his more recent publications and papers show. By all who knew him Donnan was rightly regarded as a man of outstanding ability and great promise, and it was with some misgivings that his friends learned of his decision to do his life work as a country practitioner in his native town of Holywood. When, however, his fifty years of active practice are rightly assessed there can be no regret at this decision. He brought to bear on his extensive practice untiring energy, great judgment, and a thorough knowledge of medicine: all his work was good work well done, and there are many in the Holywood district who have reason to regret his death and revere his memory. He leaves a widow and two sons, who are both in practice in Holywood; to them we offer our sincere sympathy.

The Services

Colonel S. W. Kyle, retired, late R.A.M.C., has been appointed a Deputy Director of Medical Services, and has been granted the acting rank of Major-General.

ARMY AWARD

The D.S.O. has been awarded to Lieut. James Morton Muir, R.A.M.C., in recognition of gallant and distinguished services in the field. The published announcement of the award said: "During the battle of Sidi Barrani in December he was severely wounded in the shoulder and pelvis by splinters of a shell which hit the regimental aid post vehicle. He insisted on being propped up beside his vehicle, refusing an injection of morphine so that his senses might remain clear. Though suffering intense pain he continued for approximately eight hours to give directions on the care of the wounded as they were brought in until loss of blood made it impossible for him to remain sitting. He was laid down, but continued to give directions and advice until the last wounded man had been evacuated, and only then did he consent to be placed in the ambulance. His devotion to duty undoubtedly saved many lives and was a tremendous inspiration to the personnel of the post and to the wounded men."

CASUALTIES IN THE MEDICAL SERVICES

Royal Navy

Surgeon Lieut. JOHN FFRANGCON ROBERTS, R.N.V.R., the elder son of Dr. and Mrs. Ffrangcon Roberts of Histon, Cambs, is reported missing, believed killed, in the Middle East last month. He was 25 years of age, and received his medical education at the London Hospital, qualifying M.R.C.S., L.R.C.P. in 1939. He had held the posts of resident anaesthetist and receiving-room officer at the London Hospital and resident medical officer at an E.M.S. hospital.

Probationary Temporary Surgeon Lieut. WILLIAM GRAHAM CUTHBERTSON, R.N.V.R., is included as "Killed" in an Admiralty casualty list published on March 24. He was 24 years of age, and was educated at Annan Academy, Stewart's College, Edinburgh, and the University of Edinburgh, where he graduated M.B., Ch.B. in 1939. He held a house post at St. Luke's Hospital, Bradford, before joining the R.N.V.R. in April, 1940. He saw service along the Libyan coast and was present at the action at Taranto.

Royal Army Medical Corps

Lieut. DONALD ALFRED BIRD was killed in France on June 18, 1940. He was born in Canada in 1914, took the Scottish triple qualification in 1939, and joined the British Medical Association in the following year.

Wounded

Captain Victor James Keating.
Lieut. Alexander Wilson Forbes Catto.

DEATHS IN THE SERVICES

Surgeon Captain EDWARD JOHN MORLEY, R.N. (ret.), died at Bournemouth on March 13. He received his medical education at Guy's Hospital, and took the L.R.C.P. in 1878, the M.R.C.S. in 1879, and the F.R.C.S. in 1891. Entering the Royal Navy soon after qualifying, he attained the rank of fleet surgeon in 1899 and of surgeon captain in 1910. He served in the war of 1914–18, receiving the medals.

Colonel THOMAS HENRY MATTHEWS CLARKE, C.M.G., C.B.E., D.S.O., late R.A.M.C., died at Rathfarnham, Co. Dublin, on March 4, aged 71. He was born on June 15, 1869, at Nassau, in the Bahamas, the only son of Staff Surgeon T. M. Clarke, A.M.D., who died there soon afterwards. He was educated at Trinity College, Dublin, where he graduated M.B., B.Ch., B.A.O. in 1895. Entering the Army as surgeon lieutenant in 1897, he became lieutenant-colonel in 1915, colonel in 1918, and retired in 1920. He served in the action at Kandia, Crete, on September 6, 1898, when he was wounded, and was mentioned in dispatches in 1899, receiving the D.S.O. From 1900 to 1903 he was Personal Physician to Prince George of Greece. He was seconded for special service under the High Commissioner for Crete from 1901 to 1903, and for his services received the C.M.G. in 1903 and was appointed a Knight of the Order of the Saviour of Greece. In 1912 he became physician and surgeon to the Royal Hospital at Kilmainham, a post which he held until the war of 1914–18. During that war he served in France and Flanders, was mentioned in dispatches, and received the C.B.E. He was the author of an article on sanitary work in Crete, and contributed a paper on prehistoric sanitation in Crete to the *British Medical Journal* in 1903. He had been a member of the British Medical Association for forty years.

Lieut.-Colonel HENRY WARWICK ILLIUS, C.I.E., I.M.S. (ret.), died at Funchal, Madeira, on February 13, aged 65. He was born at Bahia, Brazil, on October 9, 1875, received his medical education at St. Bartholomew's Hospital, and took the M.R.C.S., L.R.C.P. in 1900 and the F.R.C.S.Ed. in 1906. Entering the I.M.S. as lieutenant in 1901, he became lieutenant-colonel in 1920, and retired in 1930. Most of his service was passed in civil employ in the United Provinces, where he was on plague duty from 1907 to 1909, when he obtained a civil surgeoncy and held civil appointments until his retirement, except that from 1914 to 1921 he was on military duty. He served on the North-West Frontier of India in the Waziristan Campaign of 1901–2 (medal with clasp); in the Tibet War of 1903–4 (medal with clasp); and in the war of 1914–18. in Iraq in 1920–1, when he was twice mentioned in dispatches and received the C.I.E. He was a brother of Lieut.-Colonel J. W. Illius, I.M.S. (ret.). He had been a member of the British Medical Association for thirty-seven years.

Lieut.-Colonel HAROLD EDGAR PRIESTLEY, C.M.G., R.A.M.C. (ret.), died at Yateley, Hants, on March 16, aged 62. He was born on January 24, 1879, received his medical education at St. George's Hospital, and took the M.R.C.S., L.R.C.P. in 1905. Entering the R.A.M.C. as lieutenant in 1905, he became major in 1915, lieutenant-colonel in 1930, was placed on half-pay on account of ill-health in 1932, and on the retired list later the same year. He served in the war of 1914–18, was mentioned in dispatches in 1918, and received the C.M.G. for his services in the typhus epidemic at Wittenberg during that war, when some 15,000 British prisoners of war were confined in a camp of some ten and a half acres at Wittenberg and were insufficiently clothed and half-starved. Typhus broke out in the camp, the German medical staff refused to attend the patients, and all communication with the camp was cut off, food being sent in by trolley and orders shouted from outside. Six R.A.M.C. officers volunteered to attend the men, and three of the six died of typhus. Major Priestley survived, but his health was permanently affected, though he put in a further fifteen years' service. Among appointments which he held later were those of medical officer of the Duke of York's Military School at Dover and medical officer of the Royal Military Academy at Woolwich.

Universities and Colleges

UNIVERSITY OF BIRMINGHAM

Lectures in Industrial Medicine

A course of six lectures in industrial medicine for medical officers appointed to factories will be held in the Medical School on Saturday and Sunday, April 19 and 20. The course will be open also to all members of the medical profession interested in the subject. Further particulars may be obtained on application to the Dean of the Faculty of Medicine, the Medical School, Birmingham, 15.

UNIVERSITY OF LIVERPOOL

The following candidates have been approved at the examinations indicated:

FINAL M.B., CH.B.—*Part I:* [1]D. Annis, A. Ansell, E. R. Banner, [1]Beryl R. Bentley, [1]Margaret J. Blackburn, K. W. Boggis, H. O. M. Bryant, E. Burman, [1]E. F. B. Cadman, [2]Eva V. Cooper, K. H. Dalrymple, A. S. Davidson G. Davies, [1]J. N. Dearnaley, J. F. Doherty, K. E. Donnellan, Ann Donnelly, I. H. Foy, H. Francis, H. G. Frank, [1]H. Friend, [1]S. M. Green F. D. Griffiths, Elizabeth M. Harper, A. Jolleys, Eirwen M. Jones, [1]S. E. Keidan, [1]H. Lewis, I. P. Madhok, Margaret L. Magee, A. W. Merrick, A. F. Murphy, [1]R. C. Nairn, K. H. Oldfield, C. Pownall, N. E. Raybould, R. L. B. Roberts, A. J. Robertson, P. L. Robinson, M. J. R. Ryan, Betty Schofield, E. Scott, E. R. Shepherd, K. H. Slatter, H. O. Williams, [1]Margaret Woolfenden. *Passed in Individual Subjects:* Mary A. R. Allan (Pharmacology and General Therapeutics). *Part II:* E. H. Annels, A. S. Beadel, J. J. Bligh, [1]S. Bradshaw, Hilda E. Bullen, E. R. Carter, W. P. Clothier, V. L. Cooper, H. V. Cross, J. G. K. Dean, P. J. Devlin, Jean M. Frazer, K. C. Fulton, Patricia F. M. B. Gould, Joan O. Grant [1]T. C. Highton, M. Horwich, R. D. Holston, H. P. Hughes, F. A. H. Inman, W. B. E. Jones, J. J. Lieben, J. Littler, M. L. P. Lyons, Jane C. S. Maclachlan, [1]L. Mandel, A. J. Marsden, R. H. Martin, R. H. Maudsley, Betty W. Morris, P. D. Moss, J. C. B. Murphy, S. P. C. O'Reagain, C. Pownall, G. J. Rees, Hilda M. Reese, G. C. Roberts, C. D. Rosenwald, D. I. Rowlands, J. M. G. Sarsen, T. L. Schofield, Irene W. Simpson, R. V. Tracy Forster, Anabel M.

urner, D. C. Watson, R. H. Watts, G. A. Wetherell, D. W. Wilson, H. S. L. Young, [2]Rosalind Zalin.

DIPLOMA IN TROPICAL MEDICINE.—P. Austin, P. R. Cooper, I. K. Menon, L. Merrill, G. Prasad, W. B. Young.

[1] Distinction in pharmacology and general therapeutics. [2] Distinction in pathology and bacteriology. [3] Distinction in public health. [4] Distinction in forensic medicine and toxicology

UNIVERSITY OF SHEFFIELD

The following candidates have been approved at the examinations indicated:

M.D.—M. B. Brody.

FINAL M.B., CH.B.—*Parts II and III*: *E. H. Jones, *M. Laird, J. H. Foggitt, P. S. D. Gowers, J. D. Hopewell, J. R. Horn, N. R. Marshman, Joan Pattison, F. Rudnicki, C. H. B. Sparrow, P. Turner.

* With second-class honours.

UNIVERSITY OF EDINBURGH

At the meeting of the University Court on March 24, with the Principal, Sir Thomas Holland, in the chair, regulations for the Whaitt Research Scholarship Fund were adopted on the recommendation of the Senatus. The free income of the fund is to be used to provide one or more research scholarships in some branch of medicine to be chosen from time to time by the University Court on the recommendation of the Faculty of Medicine and the Senatus. The subject, conditions of award, amount and duration of each scholarship will be advertised beforehand. Graduates in any faculty of the University or of other approved universities, or licentiates of approved colleges, will be eligible for the award of a scholarship.

UNIVERSITY OF DUBLIN

SCHOOL OF PHYSIC, TRINITY COLLEGE

The following candidates have been approved at the examinations indicated:

M.D.—G. J. Dixon, R. T. Jackson, P. A. McNally.

FINAL MEDICAL EXAMINATION.—*Medicine, M.B.*: [2]B. W. Wyllie, [2]E. D. Kerr, [2]Alicia G. Pike, M. E. Weiner, W. G. D. Caldwell, A. F. Crowley, H. H. Robinson, J. R. Healy, H. B. C. Houston, W. J. Thompson, I. Shribman. *Surgery, B.Ch.*: M. A. Majekodunmi, J. L. Handelman, Kathleen M. Patterson, N. H. Stewart, A. H. H. Guilbride, L. C. Jacobson, S. Smullen, A. F. Crowley, C. D. MacCarthy. *Midwifery, B.A.O.*: [1]G. B. Gibson, [1]Elizabeth D. L. Simpson, [2]S. T. McCollum, [2]G. S. Prince, [2]Maude F. P. Bigger, [2]Emmeline P. Crowe, [2]Kathleen M. J. Morphy, [2]P. C. Smyly, [2]Margaret F. Y. Dixon, [2]J. B. Dunlop, [2]J. R. Hassard, [2]M. J. M. Solomons, J. P. Hearne, J. P. Walsh, Helen S. Watson, T. A. H. Black, C. R. Griffin, Ivy K. Bayne, Ethna M. MacCarthy, L. H. Shrago, Gladys M. Byers, L. H. Citron, A. C. MacA. Hobson, G. F. Shaw, B. Kernoff, A. McC. Russell, R. O. D. Reid, J. N. Greene, T. L. Kelly, A. G. Lee, Dorthy H. Wester, C. E. Williams, A. C. McReynolds, T. J. N. Bates, H. Lesselbaum, C. W. Lloyd, A. R. B. Jackson, D. J. Naughton.

D.P.H.—*Part I*: [1]W. Hayes, [2]F. W. Crook

[1] With first-class honours. [2] With second-class honours.

Medical Notes in Parliament

Adjustment of Financial Liabilities due to War

Moving in the House of Lords, on March 25, the second reading of the Liabilities (Wartime Adjustment) Bill, Viscount SIMON said that owing to the shifting of population a large number of people who before the war carried on the professions in the ordinary way had been put into extreme financial difficulty. The Bill applied to "any person who is in serious financial difficulties owing to war circumstances." That person might be a professional man whose clients or whose patients had moved elsewhere. The Courts (Emergency Powers) Act would in proper cases prevent the imposition of damages or distress for rent, but under it the debtor saw piling up over his head a mountain of obligations. To make him go through the Bankruptcy Court was inappropriate. The Bill provided machinery for bringing together the debtor and his creditors for the purpose of seeing, with the help of a liabilities adjustment officer, whether an arrangement could be reached to the benefit of both debtor and creditors. If all agreed a scheme would become operative at once. If a majority agreed the adjustment officer could approve a scheme, but a minority creditor could secure a review of the matter by a county court judge. There would always be priority for one year's taxes and for debt in the nature of wages. In cases where the adjustment officer had not produced agreement the county court could be invited by the debtor or by any creditor to devise a liabilities adjustment arrangement. The home and furniture of a debtor and the tools of his trade would be exempted from the property to be realized. In exercising its powers the court would have regard to the prospects of the business.

The Bill was read a second time

State Medical Service

Mr. LYONS asked on March 26 whether Mr. Ernest Brown would consider as an early post-war scheme of reconstruction the establishment of a complete State Medical Service incorporating clinical, specialist, and scientific facilities in a nation-wide proposal of general application. Miss HORSBRUGH replied that the importance of the facilities to which Mr. Lyons referred would not be overlooked, but Mr. Brown was not in a position to make a statement at present as to the form in which such facilities could most suitably be provided.

Gas Warfare

Replying on March 27 to Mr. Simmonds, Mr. HERBERT MORRISON said this country would in no circumstances be the first to employ gas. The civilian gas mask, when properly used, gave full protection against any known war gas. The Government was taking fresh steps to ensure that every member of the population carried, practised with, and was in every respect familiar with his gas mask. Exercises and propaganda would be employed to this end. With proper measures of protection such as were now available to the population there was no ground for serious alarm about the effect of gas attack, provided always that proper precautions were taken and that the public obeyed the advice given to it. Mr. Morrison added that it was not considered necessary to make a general issue of eye-shields to the public at large.

Annual Report of Ministry of Health: Wartime Cessation

Asked by Mr. Rhys Davies on March 27 when the annual report of the Ministry of Health for 1939–40 would be published, Mr. ERNEST BROWN said he regretted that in view of the work involved, the pressure under which the staffs of the Ministry and of local authorities worked, the shortage of paper, and other difficulties, it would not be practicable to continue the publication of annual reports during the war. Following the practice adopted in the war of 1914–18, material was, so far as circumstances permitted, being collected for publication in a composite report after the end of the war. He would look into the possibility of giving a summary.

Registration of Alien Doctors

Sir HENRY MORRIS-JONES suggested on March 27 that the arrangements for allowing alien allied doctors in this country to help in the joint cause by becoming temporarily registered medical practitioners were slow and unsatisfactory. Mr. BROWN answered that the Central Medical War Committee, which acted as a clearing house for supplying alien doctors to hospitals and other authorities desiring to employ them, had received a large number of names from various sources. It would be glad to receive others from the Allied Governments concerned, with some of which it was already in touch. The procedure took some time to set in motion, including as it did the steps necessary for registration with the General Medical Council and for satisfying the general requirements relating to aliens. It was now working smoothly.

Replacement of Civilian Medical Practitioners by R.A.M.C.

On April 1 Captain MARGESSON, in reply to Miss Ward, who asked for an assurance that no action would be taken against civilians reporting on conditions in the Auxiliary Territorial Service through parliamentary channels, said he was assured that Miss Ward was referring to a misunderstanding which arose out of a long-standing decision to replace civilians by R.A.M.C. women doctors, where available, on the panels formed to examine A.T.S. recruits. Notice of the

termination of their appointments was sent simultaneously to all the civilian members concerned, and there was therefore no question of discrimination against an individual.

Replying to a further question by Miss Ward, Captain Margesson said that the decision to replace civilians by R.A.M.C. personnel was taken partly because the method of payment of civilian doctors was unsatisfactory and partly to economize in medical personnel.

Fatigue in Factory Workers.—Answering Mr. Rhys Davies, Mr. ERNEST BEVIN said on March 13 that factory employers were encouraged, as a part of their arrangements for proper supervision in the interests of health and efficiency, to keep records of sickness and absenteeism which might afford indications of excessive fatigue or of something else amiss in a factory or in a particular department of it. It would not usually be possible without close inquiry at the particular factory, which would primarily be a matter for the management, to ascertain how far any evident fatigue or ill-health or accidents were attributable to speed of working as distinct from long hours and other factors. The importance of optimum rates of work from the point of view both of efficiency and of accident prevention was stressed in the Industrial Health Research Board Report on Industrial Health in War, which received wide publicity, as well as in other publications.

Home Guard Casualties.—Mr. ERNEST BROWN stated on March 25 that the air-raid precautions services are to cater for casualties among the Home Guard as they do for civilian casualties. The decision is being made known by his Regional Officers to local authorities concerned. He added that there was no need to establish additional first-aid facilities to meet the needs of Home Guard units. Arrangements for augmenting, if necessary, the personnel attached to existing first-aid posts and for paying the necessary remuneration were being made known by Regional Officers to the local authorities.

Procedure for Recruitment of Doctors.—Mr. BROWN told Mr. Groves on March 25 that the procedure adopted by the Central Medical War Committee and the Local Medical War Committees in selecting doctors for recruitment to the Forces provided for a full investigation in each case of the needs of civilian practice. The local committee invited representations both from the doctor himself and from interested parties, such as his partners, or, if he was an assistant, his principal, a hospital or any public authority by which he was employed, and, if he was an insurance practitioner, the Insurance Committee. These recommendations were fully considered, and if so desired were made orally. If the local committee recommended recruitment, objecting parties might make representations to the central committee in the same way.

Shortage of Mental Hospital Nurses.—On March 27 Mr. Brown was asked by Mr. SORENSEN whether he was aware of an increasing serious shortage of male and female nurses in mental hospitals owing to their voluntary or compulsory transference to military or war work. Mr. BROWN said he knew that difficulties were in some cases being experienced in this as well as other services administered by local authorities. The matter was being kept under review in consultation with the Ministry of Labour and National Service. The Ministry of Health was in touch with the local authorities on it. In some districts this was a major problem.

Notes in Brief

Lord Woolton and Mr. Brown are consulting on the possibility of importing concentrated orange juice.

According to the latest information, 121 tuberculosis authorities out of 174 in England and Wales have made after-care arrangements. The number of new cases attending dispensaries is well maintained in urban areas, having regard to the effects of evacuation from those areas.

The weekly value of cash, clothing, food, and other allowances paid by the London County Council to their nursing staffs varies from £3 2s. 3d for probationers in training, non-resident, to £5 1s. 5d for sisters.

Arrangements for the rehabilitation of disabled ex-Service men under medical supervision are in operation by the Ministry of Health's Emergency Service and the Ministry of Pensions.

Arrangements for the fees payable for radiological examination and report on a Service out-patient to voluntary hospitals at which medical staffs are remunerated for Emergency Medical Service work on the occupied-bed basis are at present under revision.

In 1940 eight deaths were reported in the United States as directly due to the celebration of the Fourth of July with fireworks and other explosives. There were two cases of tetanus in 1940, of which both recovered, as compared with three in 1939 and two each in 1937 and 1938.

No. 10

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended March 8, 1941.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1941 (a)	(b)	(c)	(d)	(e)	1940 (Corresponding Week) (a)	(b)	(c)	(d)	(e)

* Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

The numbers of cases of measles and of whooping-cough have slightly increased during the week. Whooping-cough had the larger actual and relative increase, the increase being distributed generally over the whole country. The slight rise in the incidence of measles was mainly due to a few areas only. Middlesex had the largest increase, from 612 to 860 cases, but the most striking difference for the two weeks was seen in East Suffolk, where the notifications rose from 99 to 157. The figure for diphtheria differed by only one notification from last week's total. Scarlet fever, with 139 fewer cases than in the previous week, had the lowest number of cases recorded since the beginning of last July.

Cerebrospinal Fever

A drop in the number of cases notified in England and Wales was shown by the returns for the week ending March 8; this was followed by a further fall for the week ending March 15, but the returns for the 22nd showed a slight increase (eight cases) on the previous week. In the

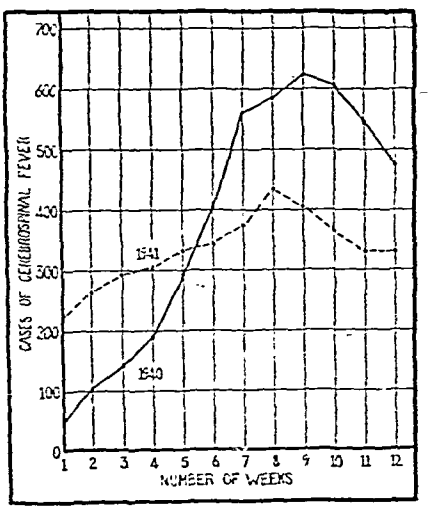

Chart showing incidence of cerebro-spinal fever in the first twelve weeks of 1940 and 1941

immediate pre-war year the weekly notifications for cerebro-spinal fever ranged from 10 to 50, with the greatest incidence in the first quarter; in 1938 and 1939 approximately one-third of the annual total was recorded in this quarter. The disease first increased to serious epidemic proportion in the second week of 1940, when 107 cases were returned as compared with 52 for the previous week. The weekly totals increased rapidly until a maximum of 623 cases was reached in the ninth week, and then slowly declined to a minimum of 107 notifications in the week ending September 7, 1940. The number of weekly cases increased slowly, and 229 cases were recorded in the first week of 1941, the beginning of the epidemic period. The rate of increase during the 1941 epidemic was very much less than in 1940, and so, despite the higher initial figure, the number of cases recorded in the sixth week was less than the number recorded in the sixth week of 1940. The trends of the two epidemics are illustrated in the chart. In Scotland the notifications have fallen from 97 to 66, a decrease of 33%.

Dysentery

A further fall has occurred in the number of notifications. All the 26 cases from Bedford were from Biggleswade R.D.; of the 15 cases in Essex, 10 were from Colchester M.B. and 5 from Brentwood; the 13 cases in Hertfordshire were all from Bushey U.D.; of the 27 cases from Lancaster, 8 occurred in Whiston R.D. and 6 in Lancaster M.B.; 9 of the 13 cases reported from Surrey came from Coulsdon and Purley U.D.; Goole M.B. accounted for 7 of the 13 cases in Yorkshire, West Riding. Of the 23 cases reported in Scotland, 8 were from Edinburgh.

Ophthalmia Neonatorum

Almost half of the cases reported in England and Wales were returned from two towns, Liverpool 13 and Birmingham 18. Eleven, almost three-quarters, of the Scottish cases were from Glasgow.

Medical News

The Pharmaceutical Society of Great Britain will celebrate its centenary on Tuesday, April 15, by a Thanksgiving Service in St. Pancras Church, Euston Road, at 11 a.m., at which the address will be given by the Right Rev. Bishop H. Crotty, Vicar of St. Pancras, and by a commemoration meeting at the Conway Hall, Red Lion Square, W.C., at 2 p.m. that day. The Lord President of the Council, the Right Hon. Sir John Anderson, will speak.

The B.B.C. announces that on Sunday, April 13, at 6.45 p.m., a talk in the Home Service will be given on "One Hundred Years of Pharmacy," by Mr. Walter Deacon, president of the Pharmaceutical Society. This is in connexion with the centenary of the society. On April 30, at 1.30 p.m., it is hoped to include a broadcast from the Red Cross stamp sale.

The House and Library of the Royal Society of Medicine will be closed for Easter from Friday, April 11, to Monday, April 14, both dates inclusive.

The annual meeting of the Society for the Study of Inebriety will be held at the Medical Society of London, 11, Chandos Street, W., on Tuesday, April 8, at 4 p.m., when Dr. J. Y. Dent will open a discussion on "The Study and Treatment of Inebriety."

A discussion on vegetables as food has been organized by the nutrition panel of the Food Group of the Society of Chemical Industry, and it will be held at B.M.A. House, Tavistock Square, W.C., on Wednesday, April 9, from 11 a.m. to 4 p.m., with Sir E. J. Russell, F.R.S., in the chair. At the morning session Dr. M. A. Pyke will speak on the chemical composition of vegetable foods and their place in peacetime and wartime diets, Dr. H. V. Taylor on the planning of vegetable production, and Miss M. Olliver on the effect of cooking on the nutritive value of vegetables. After the luncheon interval Mr. W. B. Adam and Dr. Allen will deal with the effect of canning, and of drying and other forms of preservation, on the nutritive value of vegetables. Although no tickets are required, those attending as guests of the society come under the jurisdiction of the Ministry of Home Security with regard to publication of the proceedings.

University College Hospital has arranged, with the co-operation of the Watford Peace Memorial Hospital, as a war-time measure, to open consultative out-patient clinics there. The clinics are being held as follows at 2 p.m.: surgical clinic, Monday; medical clinic, Tuesday; gynaecological clinic, Thursday. The clinics are conducted by members of the staff of University College Hospital, and all new cases attending are required to present letters of recommendation from medical practitioners.

Wynne Mariette Stuart Campbell, aged 42, described as a secretary, who, in the name of Lady Campbell, was alleged to have posed both as a member of the Secret Service and as a surgeon commander in the Royal Navy, received a sentence of three months' imprisonment at Marlborough Street Police Court, London, on March 25. Arrested at Glasgow, she was accused under the Defence Regulations of doing an act calculated to suggest falsely that she was a surgeon commander R.N., and she was charged also under the Medical Act with falsely pretending to be a surgeon.

Dr. Roscoe W. Hall, clinical professor of psychiatry at George Washington University, has been elected president of the American Psychiatric Association.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE NO.—B.M.A. and *B.M.J.*: EUSTON 2111.

TELEGRAPHIC ADDRESSES.—EDITOR, *Aitiology Westcent, London*; SECRETARY, *Medisecra Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

QUERIES AND ANSWERS

Tinct. Opii Acet.

DR. CATHERINE THOMAS writes: I shall be obliged if any reader will kindly let me know the formula for tinct. opii acetatis that was in *Neligan's Dublin Pharmacopoeia*.

Sjögren's Syndrome

DR. F. PARKES WEBER (London, W.) writes in reply to Dr. Margaret Colls (March 29, p. 500): The only English account under the above heading is by Dr. J. H. Sheldon (*Proc. roy. Soc. Med.*, 1938–9, **32**, 255). Dr. Colls does not mention the presence of kerato-conjunctivitis sicca, the feature which led Henrik Sjögren (an eye specialist in Stockholm) to make his series of communications on the subject in the *Acta Ophthalmologica*. Dr. W. Stahel, in St. Gallen, claims excellent results (*Helvetica Medica Acta*, 1938, **5**, 579) from three months' treatment with 16,000 biological units of vitamin A daily, but I have not heard that his results have been confirmed.

Conserve of Hips

MRS. DOROTHY D. STEWART, M.Sc. (Hampstead) writes: The following recipe is taken from *The Compleat Housewife*, dated 1739. The conserve prepared from hips by this method would retain the full amount of vitamin C, as no boiling is necessary during its preparation. Our ancestors seemed to realize the necessity for storing such products to be used during the late winter season.

"Gather the hips before they grow soft, cut off the heads and stalks, slit them in halves, and take out all the seed and white that is in them very clean, then put them in an earthen pan, and stir 'em every day, else they will grow mouldy; let them stand till they are soft enough to rub thro' a coarse hair sieve; as the pulp comes, take it off the sieve; they are a dry berry, and will require pains to rub it thro'; then add its weight in sugar, and mix it well without boiling, keeping it in deep gallipots for use."

Income Tax

Practice Carried On in Absence—Expenses

"LEASEHOLDER'S" practice has been carried on under the Emergency Scheme; can he still claim half annual value and rates? A ground rent is being paid for a house which has been destroyed: is this correct?

*** As regards the expenses, the answer depends on the particular facts. If the house is still being used professionally some deduction is due, but whether the half as before or not depends on what change (if any) there has been in the ratio of private to professional use. The authorities are not likely to want to drive a hard bargain in the circumstances. The liability to pay the ground rent (less income tax, of course) remains in spite of the destruction of the house; "Leaseholder" will presumably receive compensation under the proposals of the War Damage Bill, and the freeholder will be liable to bear some portion of the contributions to be levied under those proposals.

Fall in Earnings of Husband and Wife

"WIFE" explains that for 1940–1 her husband has been assessed for her salary of £500 per annum in addition to assessments of £219 and £274 for receipts from his own and her literary work. The latter items will be much reduced for 1940–1 as compared with the 1939–40 amounts on which the assessments are based.

*** There is no right of appeal at present, but if the total earnings for the actual year 1940–1 are less than 80% of the aggregate assessed (i.e., are less than £795) a reduction to the actual amount can be claimed. It is presumably for that reason that the inspector of taxes states that he can do nothing until the next return is made.

LETTERS, NOTES, ETC.

Garden Work for Convalescents

DR. SINCLAIR M. EVANS (Baslow, Bakewell) writes: In count districts we are being encouraged to dig for victory during t coming season. A good deal of extra work could be perform willingly by convalescent patients who are at present condemn to enforced idleness through the by-laws of their approv society. Surely the present state of emergency merits son relaxation of these rules at the discretion of the attendi practitioner.

Medical Woman-power

"X" writes: Knowledge that I am not the only unwanted doct gives me a small measure of consolation. Anticipating a ca upon my services I had planned my domestic arrangements s that I should be quite free to work outside my home—a difficu and expensive task these days. As I do not wish to cut myse adrift from my husband and small children I offered my servic through several channels for part- or whole-time work in m district even up to a radius of twenty miles. Apart from a sho locum and being a reserve medical officer at a small first-aid po I appear unwanted for the war effort. In this district there ar hospitals staffed by men of military age, practices are combine so that one man does the work of one or two absentees, and thi in a reception area. Retired men have returned to duties whic must be in some cases too arduous for them. There are man Service girls and, to the best of my belief, no medical woman i provided for them. Sex prejudice seems to be rife in som localities, where the medical woman is looked on as somethin out of place. Surely we are not expected to take the step back as Nazidom has, and bind ourselves to the household regardless of years spent in training and practice. I pause in my labour as cook-general to write this, as, alas! my staff have found thei services more in demand for work of national importance tha I have mine.

Calcium for Mucosal Ulcers

DR. J. SHACKLETON-BAILEY (Suffolk) writes: I have read wit interest Dr. Pappworth's article on cyclical mucosal ulceratio (February 22, p. 271), and also the recent articles on calcium absorption and metabolism. In relation to these subjects I should like to record a case of mine in which the mucosal ulcers immediately retrogress on administration of "ostocalcium" tablets. This patient, aged 60, had been troubled by the condition for about thirty years in spite of a variety of treatments prescribed by practitioners and consultants. Prior to the menopause a new crop of ulcers occurred just before each menstrual flow. Since then, I believe, their appearance has been quite irregular.

Induced Hyperaemia with Sulphanilamide in Paronychia

DR. H. G. LANGDALE-SMITH (Tarrington) writes: In the last few months paronychia has been prevalent. Although sulphanilamide applied locally and by the mouth did not appear to have much effect, it was found that by inducing hyperaemia by Bier's method to the affected limb at intervals of two, four, and six hours after the administration of 1 to 5 grammes of sulphanilamide by the mouth good results were obtained. Presumably the concentration of sulphanilamide was greater in the congested area than in the rest of the circulation. During the administration of sulphanilamide it is usual to exclude salts as well as eggs and onions, on the assumption that they contain sulphur. It seems, however, unlikely that salts are altered chemically in the bowel, and I learnt from one authority that sulphur is liberated in the bowel by any aperient, and therefore it is only necessary to exclude salts on account of their aperient action. It would be interesting to know if any untoward results have been noticed in diarrhoea when sulphanilamide is taken.

Medical Advertisements by Post

DR. W. ST. AUBYN HUBBARD (Falmouth) writes: This morning I received another batch of advertisements from various firms, all of which were promptly put into the waste-paper basket. Most of us have this bother. But what a waste of paper, cardboard, and time—especially just now! I suggest that the time is ripe to ask the principal firms upon whose products we have always relied to give up their rather childish pictorial advertisements and limit themselves to plain statements of facts on a standard size of thin card, preferably small postcard size, which we can file neatly if we wish to do so. If the big firms would only arrange among themselves to do this we could safely consign all other advertisements to the waste-paper basket without perusal. This would save the profession a tremendous amount of time and annoyance during the year.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY APRIL 12 1941

EFFORT SYNDROME IN SOLDIERS*

BY

JOHN PARKINSON, M.D., F.R.C.P.

Physician to the Cardiac Department of the London Hospital and to the National Heart Hospital; Consulting Cardiologist to the Royal Air Force

The problem of effort syndrome arises from the urgent need for men, and so it is first of military and secondly of medical importance. In war a maximum number of soldiers must be drawn from the mass of civilians accustomed to peace. The majority change over successfully from the occupations they had chosen, and by time and training become fit and often eager soldiers. But such a shift from home and work to a novel and strenuous life with drill and marching with heavy equipment is not possible to everyone, and it is disagreeable to some. All men are not equal under the test of war. Symptoms that were absent or so unimportant as to be ignored in peacetime begin or become aggravated under the stress of war. If a recruit has acquired no liking for soldiering he will complain the more easily and persistently. However that may be, he may be forced to admit his incapacity by complaints so similar to those of others that they are clearly genuine.

As the human organism does not give way as a whole, even when the whole being is on trial, one organ or system will first betray distress. It is commonly the nervous system—not surprisingly, because of the difficulty of adjustment to war and because nervous disorders are already so widespread in civil practice. In others the heart—or rather the circulatory system—will testify to the stress and present the symptoms. These may so strongly suggest a heart disease that only a painstaking examination will exclude it. D.A.H. (disordered action of the heart), now officially styled effort syndrome, was not invented by the R.A.M.C. in the last war; it was thrust upon them and so labelled in default of a better term. It is true that about a half had similar symptoms in civil life, but these were rarely combined to give a composite picture like that of effort syndrome in the Services. It constituted a big military problem because of the wastage of men it caused. Investigation showed there was no demonstrable organic heart disease. Questioning alone cannot distinguish these cases of effort syndrome from those of early valvular disease (V.D.H.). The part played by the nervous system, especially in the realm of psychology, was admitted, and influenced treatment, but it was insufficiently studied in the war of 1914–18.

The failure of heart disease is not the only way the circulation fails to respond to stress. With his nerve impaired the athlete may be dead-beat from an extreme test of endurance. He is exhausted and breathless, his heart is racing, and it is reasonable to believe that it is the circulation which sets the limit. Other systems—the vasomotor, the endocrine, and the respiratory with its chemical regulation—will share in the test and doubtless in the failure, but the reserve power of the heart is that which ultimately rations output. In effort syndrome we are dealing with men of every degree of non-athleticism and of physical and nervous inferiority, and when they undertake more than their low capacity for effort they also fail with exhaustion, dyspnoea, and palpitation—proof enough that their circulatory system cannot cope with the strenuous task of a soldier. Again, as in the athlete reaching his limit, the other systems named will doubtless take part in failure of the co-ordination which is essential to purposeful effort. An expression of this idea is seen in the term "neurocirculatory asthenia" (N.C.A.), applied in the United States to the condition we call effort syndrome. Our own term is not ideal, for it might suggest that in effort lies the origin of the disability, whereas effort merely reveals it. Further, the symptoms, while accentuated by effort, are often present at rest. But we are well rid of the terms "soldier's heart" and "D.A.H." Allbutt said that as "a series of symptoms recurring with a fair uniformity" he did not hesitate to look upon it as a disease. Its true nature is not yet known, but the full picture which bulks in war is only sporadically encountered in peacetime. Tentatively I would define effort syndrome as a *functional circulatory disease, most evident on exertion, unmasked or produced by war service.* It is hoped that the experience of this war will provide a better name, a more satisfying definition, and a clearer understanding of this condition.

The rarity of effort syndrome in the Navy and its infrequency in the Air Force have been much remarked, and the explanation is not obvious. Volunteers are in greater proportion in these Services; besides, they do not demand so uniform or so arduous a training of such a multitude of men for the toil of marching with heavy equipment.

The type of effort syndrome will vary to some extent with the kind of warfare being waged and with the class of patient studied by a particular observer. Thus in 1916 in France the soldiers were regulars or volunteers who had been fully trained, and many had been long and honourably engaged in trench warfare. The infectional group was fairly large, and the nervous group seemed smaller than the constitutional. In contrast, at the end of that war most men with D.A.H. returned to some civil employment and got well, many soon ceasing to be eligible for pension. The residue was largely composed of psychoneurotics, still clamant for their pensions, and psychotherapists were engaged in describing and treating this group. It cannot be doubted, too, that men originally reporting sick with typical effort syndrome may, with protracted idleness and numerous hospital transfers, acquire neuroticism as a sort of parasite.

In the present war, conditions so far seem to have produced a preponderance of the psychoneurotic type, and a greater proportion of those who had similar symptoms

* Based on a lecture given before the Royal Air Force Medical Society at Halton in October, 1940.

in civil life. Indeed, some current opinion is inclined to the view that effort syndrome is simply a psychoneurosis. It is not certain how far this definition will carry us, because the term can be so readily applied to any form of ill-health which is imperfectly understood and unaccompanied by organic signs. After all, psychological variations and faults in healthy people are common enough. It could only be a bar to medical progress if psychoneurosis (or psychosomatic disease) remained a label and became a dumping-ground for most unexplained illness, much as did "neurasthenia" in the past. It is still to be decided how far psychotherapy is rational and effective treatment; besides, an explanation for the predominance of circulatory symptoms, the relation to effort, and the relative uniformity of the clinical picture is not yet forthcoming. Certainly the time is ripe not only for psychological but for other investigations, as it would appear that autonomic nervous, endocrine, respiratory, and metabolic factors may also operate in effort syndrome, and will also engage the attention of the physician seeking a wider conception of its essential features. Doubtless this expanded approach has much to commend it, and will deepen and broaden our vision of what is at present obscure in the rationale of effort syndrome.

Aetiology

It is a fact that many, perhaps half, of the patients with effort syndrome give a circumstantial account of some similar symptoms in years preceding the war. These have seldom had the characteristic grouping or been severe enough to interfere with a sedentary occupation, to which indeed men may have drifted because of physical limitations. In civil practice the composite picture of effort syndrome seldom appears, or it is lost among the familiar but ill-understood symptoms which baffle doctors. It never obtrudes as a large and urgent problem in peace as it does in war. No fewer than 44,000 soldiers became pensioners for effort syndrome after the war of 1914–18.

The causes are often multiple, and this should be remembered in any attempted classification.

1. Constitutional

A man may be so ill-endowed in his physical frame or in his nervous make-up (and maybe in both) that he is thereby unfitted to become a soldier. A wretched upbringing, a poor physique, and a lack of vigour may be his permanent handicap. He may never have proved strong, either for games at school or for heavy work later. He is constitutionally a weakling, inapt for war, and training will never make him fit for it. If this could have been recognized at his first medical board he would have been rejected on this score, and there would have been one less of the "effort syndromes" in the hospital, before the medical board, and as an aspirant for a pension.

2. Psychoneurotic

From a faulty heredity, from maladjustment to the problem of living, from subconscious repressions, inhibitions, and conflicts, from excessive anxiety or hardship, singly or combined, a man may suffer from some psychoneurosis, commonly an anxiety neurosis, and his symptoms may arise entirely or partially from this cause. A few realize their inferiority and develop the complex with its sapping of nervous stamina. The cardiac bias is hard to comprehend, but it may originate in the special physical demands upon a soldier, especially when clad and cumbered so unlike an athlete. The neurotic, however strong physically, seldom succeeds in athletics.

Here should be mentioned the factor of like or dislike for soldiering. Some find in it a virtue and a fulfilment, better health and good comradeship, and occasionally a solution of some personal or even domestic problem. Quite a number of men, not cowards, dislike the idea and still more the process of training and discipline, which are essential. With no zest for the fight, and lacking spirit if not courage, they take refuge in sickness as a means of escape. Occasionally, too, there are men convinced by some careless or ill-founded suggestion of a "weak heart," and by past restrictions, that it is unsafe or beyond their powers to undertake full exertion. Related to this class are those whose nervosity is side-tracked into a belief or a cherished dread that their heart is diseased, and who cannot be dissuaded from that obsession. Such cases have been termed cardiac neurosis proper. More numerous are those who cling to the idea of heart trouble to escape what unhappily exposes them to scorn by the laity, the imputation of neurosis. Incidentally, knowing the explanation to be inadequate, we should not be misled by the man who ascribes his condition to some event, such as a minor infection or accident, which coincided with and perhaps faintly determined the onset of his symptoms.

3. Infection

The incidence of rheumatic fever in the history of soldiers with effort syndrome is higher than in that of healthy soldiers. In a control series of 1,000 slightly wounded men 5% gave a circumstantial history of acute rheumatism or chorea, while 12% of 500 men with effort syndrome gave that history. This almost suggests that rheumatism can produce, without valvular lesion, a permanent but minimal grade of myocardial inferiority. If it does, nothing would prove it so well as the ultimate development of auricular fibrillation, paroxysmal or established, in those suspected of such occult rheumatic myocardial involvement. The history of older patients contracting fibrillation, and having no other mark of rheumatism, not infrequently does include rheumatism in childhood. But the hypothesis lacks proof. The interesting suggestion has been made that the greater incidence of a rheumatic history in effort syndrome is explained by the meticulous precautions to which they have been subjected. Thus after uncomplicated rheumatic fever a boy is sometimes forbidden school games for a protracted period, losing their benefit, besides acquiring an unfounded distrust in his cardiac capacity. This may explain some cases, but hardly all.

There is no doubt that recent infections may occasion symptoms of effort syndrome when the convalescent returns too early to physical exertion. It was a commonplace in the war of 1914–18 for a soldier to contract P.U.O. (pyrexia of unknown origin) in the trenches, return to a base hospital, then to a convalescent depot, from which he was too soon drafted back to the line owing to urgent need for fighting men. He often returned quickly to the base with typical symptoms. In the Middle East amoebic and bacillary dysentery similarly proved a potent source. The lesson is clear: adequate convalescence after general infections in soldiers pays by preventing effort syndrome. Indeed, this has now been recognized in the excellent proposal that such men should retain the "diagnosis" of convalescence and only acquire that of effort syndrome when this can no longer be deferred. More, there is the interesting suggestion that such obvious cases of insufficient convalescence should not be included at all under any discussion of effort syndrome. Against this is the fact that the clinical picture may be identical with that of cases attributed to constitutional or psychoneurotic origins, and that it is awkward if a patient under treatment by the Medical Services is without a relevant diagnosis.

4. Myocardial Deterioration

In men over 35 or 40 the functional capacity of the heart has often appreciably lessened when compared with that at the age of 20 to 25; the more strenuous sports become unsuitable, though there are many exceptions. In reverse there are also exceptions. Many cases of coronary thrombosis have been reported under the age of 40, and so it is likely that there are lesser grades of coronary disease which contribute to or represent the ageing process as manifest in a diminished capacity for effort. Except in the extreme cases, we know little about this factor, and even less about the early effects of oncoming hypertension. The lesson is that here is an opportunity to extend our knowledge of the early effects of coronary sclerosis and of hypertension—to antedate them, as it were—for we have under medical supervision a multitude of men who would not be patients at all in peacetime, but who in war may report sick with symptoms which war effort evokes. However that as it may, if we are to contact more closely with the beginning of disease, careful cardiological examination is even more necessary in men of 35 and over than in

younger; and electrocardiography and radioscopy will metimes be needed for the purpose. The fear that a orough examination will harm by starting the idea of heart sease is unworthy and unwarranted. But morbid ideas may bred by routine and superfluous examinations, especially ien prolonged residence in a military hospital is improperly rmitted.

Symptoms

The symptoms are almost invariably multiple, and ten there is no particular stress on any one of them. he major are exhaustion, left mammary pain, palpitation, spnoea; the minor are dizziness, faintness. They are oked by exertion such as drill or marching, though later ey may recur at rest.

Exhaustion.—Nearly all complain that they are easily tired, d it may be this which limits their activity. Often a feeling lassitude makes any activity distasteful. Undue fatigue is ne of the most widespread of human complaints, and ldom does it point clearly to any diagnosis. In default signs it is often correctly attributed to the nervous factor; r it may be purely psychical, though it may equally be garded as a signal of general ill-health. Alone it should ever suggest actual cardiac disease, of which the characteristic is dyspnoea.

Left Mammary Pain.—This is a poor appellation for what common (young men excepted) in civil life yet a frequent omplaint in young men with effort syndrome. A large proortion, perhaps 40%, complain of it; indeed, this is the closest nk between the symptoms of effort syndrome and those of ivilian practice. Its site at or below the left breast, its haracter of aching with occasional stabs, its occurrence maybe or hours during rest as well as after exertion, are features hich readily and sharply contrast it with cardiac pain angina pectoris). Inveterate cases have local tenderness, as isclosed by the pressure of a stethoscope. No patient should ver be permitted to speak of left mammary pain as "pain n the heart," for it is this symptom more than any other hich suggests to him the false and dangerous idea of heart lisease. No fixation of fear should be allowed to develop rom a fixation of interest.

Palpitation.—Palpitation is consciousness of the heart's ction, and healthy people experience it under sufficient exerise or emotion. It is noticed too readily by men with effort syndrome, and may, like left mammary pain, make them loubt their heart's integrity. The conversion of a natural sensation of stress into a medical symptom depends mostly on the presence of a heightened or morbid sensibility from ill-health, and this is best proved in the cases in which actually *there is little or no tachycardia.* Compare such a sensitive man with the subject of fibrillation, who will complain of dyspnoea but often fail to notice his rapid and irregular heart. As some tachycardia, excessive on exertion, is the rule in effort syndrome, palpitation is a frequent symptom. If there happen to be a few extrasystoles these may augment it. With a given task it is most often the combination of palpitation, fatigue, and dyspnoea which defeats the patient and displays his malady.

Dyspnoea.—Although dyspnoea on exertion as a single symptom is so characteristic of cardiopathy, combined with other symptoms it appears more commonplace and less significant. It depends so much on the "condition" of healthy people and their age; it is expected in convalescents as it is in neurotics, in various infections, and in anaemias even of moderate grade. Dyspnoea is by no means always the chief symptom of effort syndrome, but it is generally included with the others. On direct inquiry it will always be admitted—impaired general health from whatever cause almost connoting short-windedness as a by-product. Interesting is the static dyspnoea (dyspnoea *at rest*) which in the absence of signs of organic disease is so often a manifestation of nervous instability or exhaustion and which is sometimes seen in effort syndrome. It may be a curious feeling of inability to take a complete and satisfying breath. This is not quite the same as "sighing respiration" (suspiration), though closely allied to it. Of course, such dyspnoea at rest without extreme dyspnoea on exertion and without cardiac or other signs is easily placed in its true category.

Dizziness and Faintness.—Dizziness may be no more than a momentary sensation of imbalance, and faintness no more than a transient sensation such as that which precedes a proper faint (i.e., syncope). They are so closely allied that patients often fail to make a distinction. Both are common in healthy people under certain circumstances and during temporary impairment of health, and especially with the weariness of increasing years. Similar sensations may swell the symptoms of effort syndrome, but they are seldom of as much account as a man may make out. Indeed, nothing lends itself so readily to exaggeration as a dizziness or faintness, for being rarely demonstrable it is difficult to disprove. It should not be fed by attention, always provided that aural and cardiovascular disease have been excluded.

Fainting or syncope is or should be a term reserved for attacks with loss of consciousness, and these are not especially common in effort syndrome: any soldier may faint on a parade ground. Syncope is one of the rarest symptoms of heart disease, though the public think otherwise. Recurrent faints are uncommon and may really be epilepsy.

Signs

Viewing the varied aetiology, it will not be expected that much can be learned from the general appearance. Some appear nervous or anxious, others are weary-looking; many look and act like any other soldier, but the seemingly well have their complaints, and looks should not heavily discount them. The examiner may judge them to be exaggerated, and occasionally he may sense a desire to shirk duty; but in fairness he must question and examine the man first as a doctor, and then assess his ailment as a medical officer.

Tachycardia is easily the commonest and often it is the only cardiac sign. It is generally moderate, at a rate of 80 to 100, though sometimes rates of 100 to 130 form a striking feature. There may be no tachycardia at all, or it may not be noticed but for the pulse count. Some tachycardia early in a medical examination is commonplace and insignificant, and some men have a higher natural rate than others. During the course of the examination, and especially with recumbency, it should disappear; if it does not, more notice—but not impressive or alarmist notice—must be taken of it. Extreme tachycardia suggests a preponderant nervous factor, in the absence of paroxysmal tachycardia and flutter and if pyrexial or thyroidal stimulation can be excluded.

Examination of the heart results in normal organic findings. The heart sounds are normal, and the loud first sound natural to tachycardia should not be misinterpreted. Similarly, a short soft systolic murmur difficult to hear can be ignored. Any wincing when the stethoscope is applied is a reminder that mammary tenderness is common with left mammary pain of long standing. The respiration is sometimes irregular or momentarily rapid under medical questioning. When dyspnoea at rest is a complaint it may be the inability to take a deep or satisfying breath or the sighing respiration already mentioned. Nervous tachypnoea is uncommon.

The blood pressure is normal. Even in young and healthy recruits, with the excitement and associated tachycardia of a medical examination, the systolic is not rarely 160 to 170, but it will fall shortly during recumbency, and the diastolic will not exceed 90. The blood pressure can scarcely be too low: certainly any figure between 100 and 110 systolic is to be regarded without suspicion and perhaps as a favourable sign. It is to be hoped that the fashion of imputing ill-health to "low blood pressure," often as a sop to the neurotic in civil life, will not extend to the Services.

Sweating may be too easily provoked, and sweat dropping from the armpits during medical examination was a familiar sight in the last war. Another sight was the

man who broke off during drill with a coarse and widespread bodily tremor; but such usually showed other stigmata of nervous unrest.

The *exertion test* has a limited but not a great value, if only because many with effort syndrome give a normal response, as in fact do some hospital patients with cardiac failure and oedema! It is better termed the pulse response test, as in the R.A.F., than the exercise-tolerance test. Such slight exercise as is used can in no way compare with the real drill or marching with equipment which originally made the man aware of his disability. The idea is that in health the pulse should return to normal within a minute of a test exertion, but there are so many exceptions to this arbitrary rule, and such wide individual variations in effort syndrome, that it takes a minor place in the summing-up and assessment. It does tell us something of the nervous control of the heart rate in a particular man on a particular occasion. More useful is the recognition of an undue degree of dyspnoea or distress from so slight an act of exertion. But here again, as in the nervous control of rate, who shall say what degree of improvement and stabilization may not be obtained by routine Army training? That is what it is for.

Differential Diagnosis

1. *Organic Heart Disease.*—The symptoms of effort syndrome are often grafted upon those of true heart disease. Whenever there is a history of rheumatic fever or chorea, or the patient mostly blames dyspnoea for his incapacity, *mitral stenosis* may be developing. Suggestive are a constant long systolic murmur or a loud first sound; and diagnostic will be the presystolic rumble preceding the loud first sound and best heard at or mesial to the apex, immediately after the subject exercises and lies half over on his left side. After the presystolic murmur there is no more authentic sign than the radioscopic—in the right oblique position, an enlarged left auricle displacing the oesophagus backwards. When the apex beat is displaced and forcible, often with a systolic murmur there, *aortic incompetence* is likely. This lesion is fairly common. With the patient leaning forward, the breath held after expiration, the observer listens intently at the aortic area and down the left of the sternum for the softly blowing diastolic murmur which follows close upon the second sound.

Angina pectoris, uncommon before 40, gives sternal pain or pain across the chest during exertion, and that as the only disabling symptom. This contrasts with the left mammary pain, an ache more or less continuous, lasting for hours and occasionally interspersed with a momentary stab, which a proportion of men with effort syndrome will report. From its position they may fear it is from the heart, especially if it occurs during or more typically after exertion. But it persists also during rest and even for a large part of the day. It may extend to the lower angle of the left scapula and occasionally above the left breast and even to the left arm, but never to the right arm or to both, or to the jaw. A simple table may help.

Angina Pectoris (Effort Angina)	*Left Mammary Pain*
Pain the only complaint.	Multiple complaints.
Uncommon below 40 years.	Age 20 to 55 years.
Sternal or across chest.	Left mammary or submammary.
Arresting pressure.	Ache (sometimes stabs).
During exertion only	*After* exertion; when tired.
Brief—1 to 5 minutes.	Continuous—hours.

Other *myocardial disease* is also rare under 40, and dyspnoea would then predominate and clinical or electrocardiographic signs would be found. Emphysema may be mistaken for it. *Paroxysmal tachycardia* is characterized by occasional attacks of palpitation with a high tachycardia (120 to 220) that begin abruptly, last some minutes or hours, and end suddenly. The sudden termination confirms the diagnosis more surely than the sudden onset. It is no more common in nervous than in other patients.

2. *Neuroses.*—When the chief complaints of a patient are of "nervousness," headache, fears, depression, weakness, and insomnia, and he presents a "nervous" manner, being restless, excitable, tremulous, and even emotional—provided other abnormal signs are absent, a doctor will recognize that he is faced with a functional nervous disorder, often an anxiety neurosis. Such is not effort syndrome. This is distinguished by an assemblage of prominent circulatory symptoms primarily related to exertion, any distinctly nervous symptoms being less troublesome to the patient and less apparent—if present at all—to the examining medical officer. This does not exclude, of course, a psychogenic element in their production. Incidentally, sleeplessness, indigestion, and severe headache are uncommon in effort syndrome.

3. *Pulmonary Tuberculosis.*—A history of pleurisy or a family history of chest trouble, with complaints of cough, wasting, loss of strength, perhaps pleuritic pain, would point to pulmonary tuberculosis. This was the only disease which counted much in the after-history of effort syndrome in the last war. The man may be thin, the skin ill fitting and moist, the pulse frequent; but tachycardia without other signs seldom implies tuberculosis. Auscultation of the lungs, the evening temperature, sputum examination, will follow. But radiography for early diagnosis is indispensable, and far more informative than the stethoscope.

4. *Hyperthyroidism.*—Especially in any high degree of tachycardia, the thyroid gland will be scrutinized; and, conversely, without tachycardia the idea of goitre may be dismissed. The subject should sit leaning forwards, raising the chin, and then swallow. The standing observer can then best see any fullness or asymmetry of the gland. There may be wasting, fine tremor of the fingers, and even a hint of exophthalmos. The hands are warm, not cold as so often in effort syndrome. The B.M.R. may help.

5. *Hypertension.*—This is so often found in middle age that it ought to prove possible to recognize the earlier stage in a proportion of the men of 30 to 40 now called to the colours. A closer study on these lines, with correlation of slight symptoms and signs (if any) with blood-pressure readings, might add much to our scanty knowledge about early hypertension. Under excitement and with tachycardia, the systolic level in health can reach 160 to 170, though subsequent readings will seldom exceed 160. But a diastolic level of 90 to 100 makes a pathological hypertension likely, and patient research might teach us much about this critical level. An obtrusive apex beat, a loud aortic second sound, and sometimes a mitral systolic murmur are well-known concomitants, and there may be albuminuria; but repeated sphygmomanometric readings alone can establish the diagnosis.

6. *Various.*—A number of other diseases figure in this differential diagnosis or bear upon it. They include chronic bronchitis, emphysema, asthma, pleurisy; anaemia (primary or secondary); renal disease; aural vertigo ("dizziness"); epilepsy ("fainting"). It may be said that malingerers are few, shirkers not a few, exaggerators common. The important tetrad in differential diagnosis is valvular disease, pulmonary tuberculosis, hypertension, and hyperthyroidism.

Prognosis

The most promising cases are naturally those of men with slight symptoms of recent origin who want to get well and remain with or get back to their comrades. Men with symptoms following close upon some acute infection will

ften lose them if they receive consideration and a suffi-ient convalescence. Where symptoms are of long standing, nd where considerable tachycardia persists, the prognosis s to improvement is poor, especially in men intent on eing discharged from the Army and therefore disposed to urse any malady instead of combating it. Those with ny long persistence of left mammary pain are un-romising. The more the nervous and psychic symptoms olour the picture the more problematic is a return to full luty. Graduated drill is intended not only as a part of reatment but as a means of sorting and assessment for rading.

The first concerted research on effort syndrome (D.A.H.), t Hampstead in 1916, was conducted on the most "typical" cases available, and the inferences therefrom as o prognosis are inapplicable to the majority. Later in the var prognosis improved, especially among men treated by nedical reassurance, drill, and games, and those who emained in France in convalescent depots. About 50% ecovered, and most of these then remained for reasonable periods at full duty in the line.

Prevention and Treatment

Prevention.—It will be to the country's advantage if ecruiting medical boards have freedom, as I believe they ave, to reject or place low in category men likely to become the subjects of effort syndrome. Such would especially be those with similar symptoms in civil life, certainly if because of them they had lost much time at work and been under their doctor or had changed their occupation. Further, weaklings of poor physique unlikely to improve by training, and those obviously of a nervous make-up, can seldom reach the highest grade of service. Nor can those with a persistent high tachycardia. For war purposes a convenient term to cover these cases would be "potential effort syndrome" (or potential E.S.).

If already accepted and serving, a man at his unit showing constant incapacity for prolonged exertion may be allotted a less onerous job in which he will prove useful instead of swelling the number with effort syndrome. It is better to keep him with the unit if at all possible, avoiding this diagnosis. If he is unfitted for the lighter work, or if none is available, the sooner he is discharged the better. The difficulty is, of course, to form a right judgment when there seems to be a studied attempt to evade service by importunity of complaints, especially as shirking in this form may become contagious. Discipline as well as encouragement is required from the medical officer, and a skilful mixture may restore and reinstate the milder cases. The importance of adequate convalescence after general infections or bronchial attacks has already been mentioned.

Treatment in Hospital, Camp, or Special Centre.—Rest in bed is absurdly out of place, and medicine is anathema. Once it is clear that there is no organic disease and the condition is properly classed as effort syndrome, further close examinations are redundant and may be harmful. The period in hospital should be as short as possible, for diminished discipline demoralizes a soldier. The heart is dismissed from the mind of the medical officer and by every means from the mind of the soldier. He is clearly told that the heart—and lungs—are sound, and that he is out of condition. He is not expected to retail his complaints again, but to get into condition and a healthier frame of mind.

Psychological methods of treatment are being tried in this war. They are likely to have much the same measure of success as they have with the common functional ill-health of practice in civil life, though under war conditions and in the mass they will be placed at a disadvantage. Many men who really want to get well and to remain in the Army are likely to be helped greatly by understanding doctors and especially by those who are experienced in psychotherapy.

Graduated drill under an intelligent and co-operative instructor is needed to promote physical fitness, and is a sound method of reassurance by implication; but games are equally important, and every incentive to recover by suggestion and distraction should be employed. Failure of such treatment will be recognized in men of good will by the production of symptoms and visible signs in the course of such retraining. It is no use taking pulse rates; undue dyspnoea, obvious distress, and abnormal exhaustion are the useful indications. It will be difficult to deal with the shirker. A capable instructor will help greatly in deciding whether further treatment is worth while in particular cases. If not, discharge or lower grading of the genuine incapable is indicated, and the sooner the better if rehabilitation in civil employment is to be accomplished. By such sorting the standard among the progressive group is maintained and encouraged. The ideal result is achieved when a man ceases to complain, willingly carries through his treatment, and acquires a healthy desire to return to and remain with his unit.

CLINICAL INVESTIGATION OF SHOCK

BY

ADRIAN C. KANAAR, M.D., M.R.C.P., F.R.C.S.Ed.

Captain, R.A.M.C.

Now that the battle is raging over home soil, treatment of casualties is simplified by having all the resources of long-established and well-equipped hospitals at our disposal. It is suggested that this advantage be exploited by making and preserving records of cases of shock. Analysis of such case records is a valuable form of clinical research, and a standard shock-record card would assist comparison of results from different methods of treatment. The making of such records would be within the scope of many medical officers in charge of resuscitation wards at E.M.S. and military hospitals and would be a practical supplement to the more detailed work organized by the Medical Research Council Shock Committee.

The advantages to clinical research of recording the pertinent data of cases of shock on a special card were emphasized by Brittain and Latter (1940), and the hope was expressed that a suitable standard card would be produced for use in E.M.S. hospitals. Moreover, apart altogether from research and private case notes, there is a need for some written record of the amount, speed, and time of transfusions, and the extent and rate of improvement in blood pressure and general condition, since such details assist the surgeon in deciding on the best moment to operate and when further restorative measures are required. Such a card has advantages over the case sheet, since it involves less descriptive writing and obviates omissions.

The Resuscitation Records Card

It was with these considerations in mind that the card here reproduced was planned during seven months' experience of keeping case records as O/C Army blood transfusion team. Although work on this card was begun in October, 1939, it has not been published before, as it seemed desirable to remould it after gaining experience of its use and after receiving the help and criticism of a number of authorities. The card may still have imperfections, but it seems best to publish it now in the hope that others may wish to use it.

A study of papers on blood and plasma transfusions shows that the value of the conclusions drawn has often been markedly limited by the small number of cases observed. In some instances (Brewer, Maizels, Oliver, and Vaughan, 1940) the numbers have been increased by pooling the results from several centres, and such a co-operative method has distinct advantages. The present card readily lends itself to organized "pooling," and i might be possible to study several thousand cases in a fe months if severe air raids continue.

As co-ordination is of importance I would be glad if al who intend to utilize this card would communicate wit me c/o The Royal Society of Medicine, 1, Wimpole Stree W.1: I would welcome any suggestions which result fron

Scale: Approximately half size of original.

their experience of its use. Cards may be obtained at short notice from G. E. Austin, 27, The Market Place, Richmond, Yorks ('Phone: Richmond 433), at 2s. 6d. for 20, 4s. 6d. for 50, 6s. 6d. for 100 approximately.

Some of the advantages obtained from the use of this card are:

1. The stiff cardboard facilitates writing.

2. The card is adaptable, and therefore equally useful to an ordinary resuscitation department or to a research team. For the latter purpose additional investigations such as blood volume, plasma proteins, etc., can be put in the "addenda" column.

3. The only special investigation requested is that of a series of haemoglobin estimations from a single site. These take very little time and are a useful guide to the degree of alteration in blood concentration effected by treatment. It is hoped to publish shortly a note on the interpretation of the haemoglobin percentage in relation to shock, and a copy of this could accompany the card.

4. Time is saved by diagrammatic indication of injuries and by use of a system of grouping of individual symptoms into (1) slight, (2) moderate, (3) severe, (4) very severe, the number being inserted in place of words.

Description of Card

The card is a single sheet of stiff white glazed cardboard, printed on both sides, which, folded in two, forms four pages, each 6 by 7½ inches. It will provide a means of assessing the value of blood, plasma, and other remedies, alone or in combination. There may be difficulty in obtaining strictly comparable cases on which to base an opinion, but this objection is more apparent than real. For example, if any combination of remedies is really better than another it should appreciably lessen the time taken to raise the systolic blood pressure to 85 mm. Hg in series of cases in which it was below 60 mm. Hg at the start of treatment. If a large enough number of cases—e.g., several thousand—were analysed after treatment by two different methods, the other variable factors, such as degree of haemorrhage, amount of trauma and pain, duration of lesion before treatment, etc., would tend to equalize out or could be analysed separately in groups. The final test is the survival rate of severe cases.

Sections B and C

These are described first, since they are the kernel of the investigation, and should be completed in all cases. Not every point in Section B need be noted at each examination. For example, if on admission a man is pulseless, with a blood pressure of 30 and a temperature of 95° F., there is no object in estimating his blood pressure or taking his temperature again until his pulse is palpable and his limbs are becoming warmer to palpation. One should just press on with energetic treatment, making every quarter to half an hour a brief record of any significant change in his vitality. Blood-pressure reading alone, without any other record of shock phenomena, would give a fair indication of the results of treatment.

Answers regarding severity or degree of departure from the normal should be classified into four groups. In general these are: (1) slight, (2) moderate, (3) severe, (4) very severe. These terms will apply readily to vomiting, sweating, pain, restlessness, and rigors. A similar system of groups can be employed for: (*a*) pulse character—(1) fair, (2) poor, (3) thready, (4) impalpable; and (*b*) limb temperature—(1) slightly cool, (2) cool, (3) cold, (4) very cold. Such a classification saves much writing, and can give quite a good mental picture of the case. The skill of the observer will increase, and the individual variations of different observers will decrease, as experience of war casualties is gained. Exact details, whenever they can be given, are preferable to grouping (e.g., "Vomited 500 c.cm. at 17.00 hrs.").

Estimations of degree of shock before and after treatment are the essentials of the investigation, and these are of a reliable objective nature, provided that the blood pressure and temperature are recorded.

Estimation of Haemoglobin.—This investigation can usually be arranged in all but the busiest times. The method used should be stated. Haemoglobin estimation will reveal the extent of haemoconcentration in shock without haemorrhage (Moon, 1938), and a series of such tests are a valuable indication of progress with regard to haemorrhage and shock when under treatment (Keith, 1919; Robertson and Bock, 1919) and also during the post-operative administration of fluids (Jones and Morgan, 1938). Interpretation, however, requires some thought, since a plasma transfusion may cause a rise of haemoglobin in a case of haemorrhage (Brennan, 1940) and a blood transfusion may cause a fall. The former anomaly is apparently due to the mobilization of red blood cells which were static in the capillaries, while the latter findings are due to stimulation of the physiological response to haemorrhage—namely, withdrawal of fluid from the tissues into the blood stream.

Addenda.—Additional facts or special investigations may be noted when desired.

Continuation sheets of Section B are obtainable, and can be pinned to the card if required.

Reactions.—These refer chiefly to rigors and to sudden dyspnoea, pain in chest, cough, and collapse, with oedema of the lungs, which may result from giving intravenous fluids too quickly. Pain in the loins, bursting headache, tingling all over the body, and collapse followed after a latent period of two to seven days by anuria (Riddell, 1939) resulting from a mismatched transfusion, would also be recorded if they ever occurred. An attempt should be made to exclude inflammation as the causative factor before ascribing rigors, pyrexia, and jaundice to blood transfusion. Suspected haemoglobinuria should be confirmed by a pathologist if possible.

Fluids by Mouth and Per Rectum.—It is important to comment on the amount given, as "forced fluids" are an important factor in speeding up dilution of the blood after haemorrhage (Robertson and Bock, 1919).

Morphine and Chemotherapy.—The relief of pain and the control of infection (especially gas gangrene) have an intimate bearing upon the degree of shock, and should be carefully recorded.

Oxygen.—Details should be given of the mask used and volume of oxygen given per minute, with the duration.

Cortin, etc.—Synthetic adrenal cortical extract may be worth a trial, in view of reported results (Scudder, 1940), especially when physical exhaustion has been a contributory factor in the condition of shock. Ergotoxine is certainly deserving of trial, as shock may be due to over-stimulation of the sympathetic nervous system (McDowall, 1940).

Section A

Additional knowledge may be gained by a careful study of causative factors in cases of shock, and a note should be made of these in Section A if there is time to do so. There will be many occasions when this is impossible, but much can be accomplished by good organization and training of the transfusion personnel. An example of what can be done under war conditions was shown in January, 1940, at a meeting of a medical society in the B.E.F. in France, when a surgeon (Challenor, 1940) who had worked at a casualty clearing station in the last war produced a book in which were entered details of all his operations. These had been dictated by him to a theatre clerk towards the end of each operation. In addition M.R.C. cards were completed for many special cases, in order to trace their course after they had left the casualty clearing station.

Sections D, E, and F

Section D: Operation.—Brief details will suffice to complete the clinical picture.

Section E: Remarks and Summary.—This should be completed after a day or two, or later if possible, to indicate the ultimate outlook of the case.

Section F.—A note of the haemoglobin two to five days after the operation, in the absence of dehydration or severe infection, will give some idea of the extent of the original

blood loss, and may be of interest in retrospect, when compared with haemoglobin readings during the phase of shock.

Suggested Procedure

(*a*) General duties orderly or clerk to complete details on top of page 1 for each case on admission to resuscitation wards.

(*b*) *Nurse or trained nursing orderly* to complete sections A, B, and C under supervision. This may be done while he is waiting for the blood or plasma to warm up and while he watches it pouring in.

(*c*) *Resuscitation officer,* (i) on admission, to take rapid history, do brief examination, and order treatment; (ii) introduce needle and collect blood for haemoglobin estimation; (iii) later read A and B and add any further comments and notes, indicating his views of the severity of the various symptoms, signs, and complaints, and ordering further treatment; (iv) complete later notes, after two to five days if possible.

(*d*) *Nurse or trained nursing orderly* to accompany severe cases during operation, to supervise transfusion, and to complete operation and anaesthetic notes and records of blood loss at operation. Where possible the nurse or orderly who has resuscitated the case should be detailed for this work to ensure continuity of treatment and interest, but if one cannot be spared the co-operation of the anaesthetist should be invited.

Summary

The desirability of a standard record card for cases of shock in E.M.S. and military hospitals is stressed.

A resuscitation record card designed for practical utility and suitable for statistical research is described and illustrated. Copies of this card are readily obtainable.

It was from suggestions of Lieutenant (now Major) H. W. Rodgers in January, 1940, that my blood transfusion record card was greatly improved.

My thanks are due to Major H. L. Marriott and Captain A. Kekwick for many helpful suggestions, and to Majors Hadley and Kimbell for repeated assistance in remodelling and improving the card.

Latterly I have had most useful advice from Prof. J. A. Ryle and Colonel L. E. H. Whitby, O/C the Army Blood Transfusion Service, as a result of which the card has been much shortened and its objective focused on results of treatment. Finally, a number of its details have been modified on advice from Prof. T. B. Davie, Dr. H. F. Brewer, and Lieut. J. B. Hurll.

In making these acknowledgments I must, however, accept full responsibility for production of this paper.

M. Schmouchkovitch (*Thèse de Paris*, 1940, No. 284) records twenty-one cases, in patients aged from 11 to 53, indicating the importance of inherited or acquired syphilis in the causation of appendicitis. Clinically there are symptoms of appendicitis—tenderness at McBurney's point and muscular resistance—which yield to anti-syphilitic treatment. Anatomically there may be a characteristic diffuse lymphocytic infiltration in the appendix, a sclero-gummatous process destroying the whole organ, gummatous ulceration of the wall of the appendix, or a plasmocytic granuloma, which is the last stage of a gumma which has perforated the muscular wall of the appendix. Lastly, the *Treponema pallidum* has been found in the appendix.

SARCOIDOSIS

SOME SPECULATIONS AS TO THE STAGES OF INFECTION IN GENERAL

BY

G. ERIC LEWIS, M.A., M.B., M.R.C.P.

Honorary Physician to the Hull Royal Infirmary and the Scunthorpe and District War Memorial Hospital

Considerable attention has recently been devoted to the condition described as the "sarcoidosis of Boeck." This paper gives details of an unusual case in which there were signs and symptoms suggestive of a "visceralization" in the central nervous system, producing the clinical syndrome known by the name of Adie.

The mere report of an unusual case is scarcely novel, but it appears that a consideration of the pathology and possible aetiology of the sarcoidosis of Boeck may well lead to an understanding of the mechanism of infection and immunity in general. Some discussion of these possibilities is attempted after a description of the particular patient.

Case Record

Mrs. A. provided a diagnostic problem lasting for nearly two years from November, 1936. She was 53 years of age when she was referred to my clinic at the Hull Royal Infirmary in that month. She had for three months past been complaining of a "blurred patch" in the lower part of the field of vision of the left eye. Apart from occasional pains in her hips and back, she presented no other symptoms of any sort. A past history of so-called "muscular rheumatism" ten years ago was elicited, but she denied any other indispositions. On examination the pupils were found to be inactive—there being no response either to light or to accommodation—and she seemed to have a tendency to Rombergism. There was, however, no sensory loss to pinprick, postural change, or vibration. The grip of both hands was firm, strong, and equal, but a slight tremor of a coarse sort and of "intention" type was noticed. The gait was fair, but although the arm-jerks were normal both ankle-jerks were absent and also the right knee-jerk. No other grossly abnormal physical signs were detected.

She was admitted to the Hull Royal Infirmary under my care on November 16, 1936, and it was found that the Wassermann reaction of the blood was negative. The cerebrospinal fluid was not under pressure and was not abnormal in respect of its cell, protein, or glucose content. The Wassermann reaction of the fluid was also negative. Further clinical examination showed sluggishness of both biceps-jerks and, later, probable absence of the biceps- and supinator-jerks. Perimetry confirmed the constriction of the field of vision of the left eye, and ophthalmoscopy presented a confusing picture. The left optic disk seemed pale and the left retinal vessels were narrowed. The appearances were suggestive of secondary optic atrophy. The veins of the right retina were engorged and the right optic disk appeared to be affected by a mild papilloedema. These findings were confirmed by the ophthalmic surgeon (Dr. Stenhouse Stewart). A radiograph of the skull (Dr. J. E. Bannen) was reported upon as showing no abnormality. Apart from a suggestion of possible neuromyelitis optica no definite diagnosis could be formulated, and Mrs. A. left the Infirmary early in December, 1936. Later that month she consulted Dr. W. Russell Brain, who informed me that he considered her to be a case of Adie's syndrome with tonic pupils and absent tendon-jerks.

The patient continued to attend my follow-up clinic, but her condition remained unchanged and no further symptoms were remarked upon until May, 1937. At this time both parotid glands began to swell. The enlargement was more pronounced on the left side than on the right, and it was not accompanied by pain, fever, or any constitutional disturbances. On June 19 the parotid swellings seemed quite unchanged. A degree of incoordination, as shown by finger-to-finger and finger-to-nose tests, was evident, but the other neurological findings, given above, were quite unaltered. A radiograph of the chest taken

at this time was reported on as showing "no evidence of any tuberculous infiltration." She was admitted to the Hull Royal Infirmary again, and a portion of one parotid gland was removed for histological examination. The appearances were diagnosed by the pathologist (Dr. W. W. Adamson) as being due to tuberculosis, but examination of the section, while showing a granulomatous reaction with giant cells, failed to reveal any definite areas of caseation. The injection of an emulsion of the pulped tissue into a guinea-pig had been suggested, but this was not performed.

During her stay in hospital on this occasion the left optic disk still seemed very pale, but the outline of the right disk was perhaps rather less blurred than before. The defect in the field of vision was persistent and unchanged. The Mantoux reaction was negative as well with a 1 in 1,000 as with a 1 in 10,000 solution of old tuberculin. The parotid swellings gradually subsided, and the patient returned to her home on September 20, 1937.

When Mrs. A. was next seen she stated that "trouble with her eyes" began about the end of October, 1937. Later she also developed pains in and swelling of the small joints of the hands. She was readmitted to hospital on January 8, 1938, with a diagnosis of episcleritis. A small portion of corneal tissue was removed by Dr. Stenhouse Stewart, and the histological appearances were again considered by the pathologist to be those of tuberculosis. It was considered, however, for reasons similar to those previously mentioned, that the appearances were more probably those of the sarcoidosis of Boeck. The Mantoux reaction remained, as before, persistently negative. Clinical examination showed some periarticular swelling of the small joints of both hands, and the neurological changes were as previously described.

The inflammatory changes in the eyes subsided fairly satisfactorily, and the following report was given me by Dr. Stenhouse Stewart: "The margins of the right optic disk are ill defined and the left disk is paler than normal, especially on the nasal side. This pallor has neither the appearance of a primary optic atrophy nor of a secondary one, the margins of the pale disk being well defined. This might, however, be possible in an atrophy secondary to a low degree of neuritis. The grosser sectoral field-loss of the left eye, being in the lower nasal quadrant, should correspond to the upper pole of the disk, but the left disk is no paler here than elsewhere. Is the visual lesion here possibly of the nature of chiasmal opto-arachnoiditis?"

Further investigations included another radiograph of the chest, which was reported on as showing no disease at all. The hands were also examined radiologically, and showed no evidence of tuberculosis, arthritis, or any bony changes. The total white blood cell count was 15,000 per c.mm., the differential percentages being: polymorphs 65%, lymphocytes 25%, large mononuclears 6%, and eosinophils 4%. An Arneth count gave a "weighted mean" (polynuclear index) of 2.68. The sedimentation rate of the erythrocytes was definitely increased (36 mm. in one hour), even although this rate was less than this (25 mm. in one hour) just before her discharge.

After her discharge the patient was seen again at my follow-up clinic. The eyes seemed much better, but the restriction in the visual field was unchanged. The periarticular changes in the hands had subsided, but the ankle-jerks and the right knee-jerk were still absent. On the whole, however, her general condition was decidedly improved.

Commentary

This patient seems to have been affected by the sarcoidosis of Boeck, and I am not aware that any case of this condition showing neurological signs and symptoms has previously been reported. It is possible that similar obscure cases may be due to similar pathological changes. Certainly, the syndrome of Adie rarely appears to have any anatomical basis, and a review of such cases (Adie's syndrome) might perhaps reveal further examples of the visceralization of the sarcoids. The above facts are merely adduced to illustrate the considerable variability of the manifestations of this condition. A full review of the subject is given by Snapper and Pompen (1938) in an excellent monograph, and this variability of symptomatology has also been stressed by Bodley Scott (1938).

It is now generally conceded that the uveo-parotitis of Heerfordt (1909) is a clinical variant of sarcoidosis. It was previously maintained that uveo-parotitis was invariably of tuberculous aetiology (Garland and Thomson, 1934), despite some evidence considered to point to the contrary (Lewis, Raines, and Stewart, 1936).

It is said that cases of sarcoidosis show a "positive anergy"—i.e., that they are more often Mantoux-negative than normal persons of the same age—and the findings in the case reported are consistent with this view. Lemming (1940) has failed to produce tuberculin-sensitiveness in cases of sarcoidosis even by the administration of living B.C.G. vaccine. Although such findings might be considered as evidence against a tuberculous aetiology for sarcoidosis, or rather as evidence of a considerable immunity to tuberculous infection, no explanation is given why a lesion in which no bacilli are demonstrable should not only persist for years but continue to develop in fresh sites. A remarkable case was reported by Wiseman (1938) in which tubercle bacilli were detected in the ulcers of the leg, said to be due to Boeck's sarcoid; but, as Ingram (1938) pointed out later, the evidence for the diagnosis of sarcoidosis was by no means conclusive.

The suggestion is made that Ranke's (1928) classification of tuberculosis may be extended and applied to almost any infection and that considerations of this sort may lead to an explanation of the above-mentioned facts. Ranke divided the tuberculous state into three stages, each characterized by its own type of tissue reaction. The primary stage, or stage of invasion, usually occurs during childhood for the majority of the population: it is symptomless and signless. In the secondary stage "tissue allergy" is said to develop, and, although it may also be symptomless, signs are present in the shape of positive tuberculin reactions. The lesions of this stage are exudative in nature—e.g., some cases of erythema nodosum, and some cases of uveo-parotitis, and even, possibly, some cases of Boeck's sarcoidosis. In the tertiary stage, with typical proliferative active tuberculous lesions, the skin tests with tuberculin may reveal a lessening of tissue hypersensitivity and an increase in tissue immunity.

It is common ground that any infection goes through very similar stages. There is an incubation period representing Ranke's first stage—the stage of invasion; and finally there is the fully developed disease. The problem of the second stage is less clear, but every physician sees many unexplained abortive cases which may well fall into this group. Cases of "threatened pneumonia" are not uncommon, and, in particular, cases of "meningism of uncertain aetiology," in which the tension of the cerebrospinal fluid is increased and yet no signs of definite disease can be made out in any part of the body, are often seen. Such cases, I consider, represent the second stage of an infection. Invasion has occurred, followed by an exudative tissue reaction, but the bodily defence mechanisms have in these particular cases overcome the invading organisms before the typical third-stage appearances of a recognized and recognizable disease have developed.

In view of Lemming's experiments it is permissible to conjecture that the second stage may be a non-specific one. Invasion may occur, and the second stage may actually be the development of either tissue allergy or anergy, according to the balance struck between the invading germs and the bodily defences. The type of tissue reaction may well be the same for all infections. Sarcoidosis may represent a typical second-stage lesion, as in my opinion does the particular type of it described as uveo-parotitis (Lewis, Raines, and Stewart, 1936). It is likely that a majority of

cases are the response of the tissues (anergy or allergy) to a tuberculous invader, but it is more than likely that the second stage in infection is a non-specific one, and that the appearances of disease of a common sort are only produced when the balance between attack and defence is so disturbed as to allow of the development of the proliferative lesions of the third stage of disease, with the characteristic tissue immunity.

Summary

An unusual case of sarcoidosis is described, with "visceralization" in the nervous system, producing Adie's syndrome. Episcleritis and uveo-parotitis occurred later in the same patient.

A general discussion of the possible mechanisms of infection is attempted, and it is maintained that conditions such as sarcoiditis represent a non-specific second stage of disease.

AN OUTBREAK OF ACUTE GASTRO-ENTERITIS AMONG TROOPS IN A LARGE TRAINING AREA

PRELIMINARY REPORT

BY

A. H. D. SMITH, *M.C.*, **T.D., M.B., Ch.B.**
Lieut.-Colonel, R.A.M.C.

AND

D. J. DAVIES, M.B., B.S., D.P.H.
Captain, R.A.M.C.

In the midsummer of 1940 a few sporadic cases of enteritis of a very mild type occurred in a military camp, and despite all efforts no causal factor was discovered. None of the cases conformed to any of the known diseases with which diarrhoea of the small-intestinal type is associated. In several there was definite enlargement of the spleen, and in one case it was palpable for several weeks. It was never tender on palpation. Agglutination tests for typhoid and paratyphoid groups and tests for *Brucella abortus* gave negative results.

From the opening of the camp in the beginning of September, 1939, no case of typhoid, paratyphoid, or dysentery had occurred until this outbreak, and none has occurred since. T.A.B. inoculations had been carefully and widely carried out, and very few, if any, of the troops were not fully covered.

About the middle of September, 1940, a definite epidemic of gastro-enteritis began, and it still persisted at the time of writing (December 18). This was not limited to the military units, but existed among the civil population in the immediate vicinity, though apparently it has not been investigated by the civil authorities.

Every effort has been made to exclude the possibility that infection has been conveyed by foodstuffs, the milk supply, or the water supply. Repeated bacteriological examinations of these sources have been made, and all have been persistently negative for the typhoid group, the *Salmonella* group, staphylococci, and streptococci. Many specimens from the food served to all ranks in the camp were examined, including meat, sausage, margarine, cake, bread, and cheese. The water supply, which came from the mains of the near-by town, was chlorinated during the period of investigation.

Among a very large number of troops about 150 reported sick, and some 30 of these had to be admitted to hospital. In addition many had had similar symptoms but of such mild degree that they did not seek medical advice. In those cases admitted to hospital every effort was made to obtain a careful history of the illness and its opening phases, and thorough bacteriological examinations were made of the faeces and the blood in the acute phase and during the convalescent stage ten days after the onset and later. All bloods sent to the laboratory were cultured. It may be noted at once that the bacteriological examination of both blood and faeces was entirely negative. Blood counts were not done, and as we were unable to obtain specimens the vomit was not submitted to laboratory examination. The history of the illness was not constant, though 60% conformed very closely to what we can call the typical case. In such a case the patient retired to bed feeling perfectly fit. In the early hours of the morning he or she would wake up with intense and urgent vomiting, followed by diarrhoea of a very watery type. There was little malaise, and the most prominent symptoms apart from diarrhoea and vomiting were mild backache and a feeling of heaviness in the abdomen. The diarrhoea varied from a few motions a day to, in one case, twenty-six motions. The stools contained no blood or mucus; they were offensive, of the typical small-intestine type, and usually chocolate-coloured. The course of the illness in its acute stage was short. Most patients had a temperature varying from 99° to 100° for from twenty-four to thirty-six hours. A few had a higher temperature, but none over 101°, and in a few cases the pyrexia persisted for seventy-two hours. There was no prostration in any case, and immediately after the acute phase all patients complained of hunger and asked for food. Convalescence was smooth and rapid, and only a few cases relapsed. Most of those infected were fit to return to duty in about a week from the onset. During the acute stage the tongue was slightly furred; redness of the fauces was often seen; there was no skin eruption or epistaxis; and abdominal palpation revealed nothing except splashing in the right iliac fossa. The spleen was never palpable. There was no distinctive feature in the pulse rate.

Atypical cases had vomiting and no diarrhoea, or diarrhoea and no vomiting, the clinical course otherwise being similar to that of the typical case. The bulk of the cases were ambulatory. In a number of atypical cases there were prodromal symptoms of a few hours' duration. These consisted of a feeling of malaise and shivering. In a series of 76 cases 50 had diarrhoea and vomiting, 6 vomiting only, and 20 diarrhoea only. The epidemic was still prevalent at the time of writing, and a few recent cases have developed respiratory catarrhal conditions either previous to the gastro-enteritis or immediately following the attack. Whether there is any significance in this it is too early to decide.

It is as yet impossible to define the incubation period with any real accuracy, but in the light of our present experience it would appear to range from thirty-six hours to seven days. Recently the cases have occurred in such a manner as to suggest that the illness is passed from patient to patient by contact infection, and we have noticed that men sleeping in beds adjacent to known cases have developed the gastro-enteritis during what we consider to be the incubation period. There is no epidemiological evidence to suggest infection from food, water, or milk as the causal factor. The outbreak has not been explosive in character and is obviously of a protracted type.

We cannot at present do more than suggest possibilities as to the cause of this epidemic. Unfortunately we have not been able to refer to the literature on this subject. We have, we believe, excluded the common causes of acute diseases of the gastro-intestinal tract—namely, typhoid, the paratyphoids, the dysenteries, and the *Salmonella* group—and food poisoning due to staphylococci and streptococci has also been excluded. The chemical causes have not yet been excluded, and this is to be part of our further investigations.

It is possible that this outbreak is of virus origin and similar to the so-called gastric influenza, or the gastro-enteritic type of distemper in dogs or swine fever in pigs. Bloods from different cases presenting the symptoms are being examined at the Wellcome Institute, London, for the possibility of virus infection, but no results are yet available. It is hoped that this preliminary paper will stimulate investigations at other stations which may have similar outbreaks, and at a later date we hope to publish further observations and to have available the results of the work at the Wellcome Institute, together with the results of blood counts and the examination of faeces and water supply for any possible chemical cause.

We wish to thank Dr. D. T. Robinson, who has worked in the closest co-operation with us in these investigations and who has been entirely responsible for all the bacteriological work; also Major-General W. Brooke Purdon and Colonel D. Ahern for permission to publish this preliminary note. We wish especially to stress how close and cordial are the relations between the emergency public health laboratory and the R.A.M.C. in this area.

THE REPAIR OF LACERATED EYES

BY

R. LINDSAY REA, M.D., F.R.C.S.

Ophthalmic Surgeon, West End Hospital for Nervous Diseases, and the Western Ophthalmic Hospital

This article may be looked upon as a plea for the saving of a damaged eyeball. I hope it will appeal to all surgeons, whether ophthalmic or general.

Many of those who are injured as the result of air raids are found to be suffering from lacerated injuries, as in the recent case of a man aged 50 who had both eyes slashed across with flying glass. The left eye was literally in ribbons and had to be removed, but the right eye showed a horizontal cut across the cornea from limbus to limbus. The edges of the wound were fairly well opposed. This condition is often found among the civilian wounded, and the requisite operation should present no difficulties to an ophthalmic surgeon. The general surgeon, however, is often tempted to remove such an eye. Instead the following procedure—known as Kuntze's operation—is recommended.

Operative Procedure

The skin of the eyelids, forehead, nose, and cheeks is carefully cleansed, preferably with merthiolate solution No. 45 (P.D.), 1 in 4,000. The lids are gently held apart by an assistant and lifted from off the eyeball to avoid all pressure and the consequent squeezing out of the contents of the eyeball. A few drops of 5% cocaine and some of the same merthiolate solution are used to clean the conjunctival sac, but washing out should be avoided. On the side nearest to the wound the conjunctiva is picked up and cut with scissors, thus forming a ribbon (Fig. 1) which can be gently slipped down over the cornea and laid over the length of the corneal wound. At each side the ribbon is held in place by a suture (Fig. 2). Soft ophthalmic boric ointment with 1% atropine is laid inside the eyelids, and both eyes are bandaged to avoid movement. A little ointment may be slipped into each conjunctival sac daily. In four to five days the sutures will cut out, and often the ribbon will retract, showing a

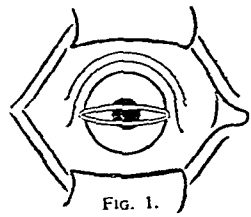

FIG. 1.

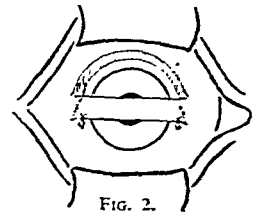

FIG. 2.

healed cornea. If the conjunctiva adheres to the wound this can be gently dissected off a few weeks later. The action of the eyelids helps in the separation of the conjunctiva from the cornea.

In the case mentioned above it was discovered, when the cornea was healed, that the lens capsule had been lacerated and lens matter filled the anterior chamber. This will be removed by a curette evacuation later on.

Sometimes a cornea will not heal, owing either to malposition of the edges of the wound or to the fact that the wound edges are not sharply linear. Here the procedure is the same at first as that already mentioned. Pressure of the eyelids on the damaged eyeball must not be allowed. A narrow strip of conjunctiva is again dissected more or less parallel with the wound. Using Traquair's conjunctival suture forceps—an instrument with a small horseshoe at the end of each prong (Fig. 3)—the edge of the corneal wound can be picked up and a fine needle passed from within outwards

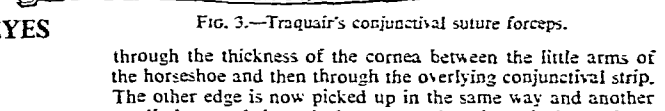

FIG. 3.—Traquair's conjunctival suture forceps.

through the thickness of the cornea between the little arms of the horseshoe and then through the overlying conjunctival strip. The other edge is now picked up in the same way and another needle is passed through the cornea, then through the conjunctival slip, and the suture is tied. (The suture, a 12-inch piece of silk threaded at each end with a fine cutting needle, is made by Messrs. Merson of Edinburgh and is used for corneo-scleral suturing during cataract operations. It bears the author's name. If not available any fine silk—say No. 00 thickness with a No. 5 or 6 squint needle at each end—will do.) The overlying vascular slip helps the avascular cornea to repair, and thus the eye can be saved. It should be mentioned that protruding iris should be gently caught up and cut away. To avoid pressure on the eyeball Arruga's speculum should

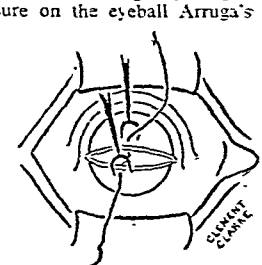

FIG. 4.

be used. This is better than using Desmarre's separate lid retractors.

The final stage of the operation, depicted by Fig. 4, is the same as Fig. 2, but instead of a suture at each end of the slip the suture will be in the middle of the slip but not quite in the centre of the pupillary area.

The largest wound of the eye ever repaired by me was a transverse cut across the cornea and as far again through the sclera. Another case was that of a machinist who was cutting tin. A strip flew out of the machine and cut the

woman's eye from the inner canthus to the outer. She had the wit not to squeeze, but just held her eyes shut. The wound, treated as above, healed, and it was then found the lens had not been touched. In spite of some lost iris she retained good vision and was able to start work again.

Clinical Memoranda

Albinism: Observations in Two Native Seychelles Families

Among many peculiarities in Nature's constructions is albinism. This subject is of some special interest, as it is seen not only in mankind but also in animals. The following observations were made on two native families in Mahé, Seychelles Archipelago, situated in the middle of the wide expanse of the Indian Ocean.

Family A.—Of this family of eight, six members are pure albinos. The father is an albino, the mother a pure negress. The first five children are albinos, the sixth a pure negress. The father is the son of a pure Frenchman from Réunion and a pure negress (a Malgache) from Madagascar. Whereas

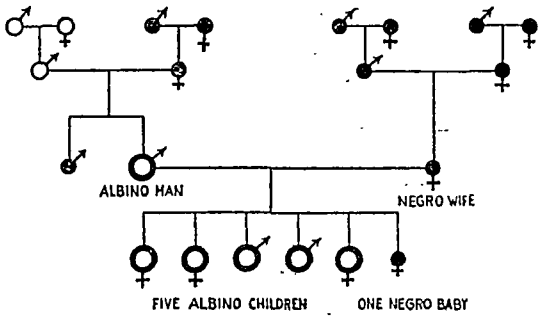

FIG. 1.—Showing genealogy of Family A. The white circles represent Europeans; the black circles, negroes and negresses; and the black circles with white centres, albinos.

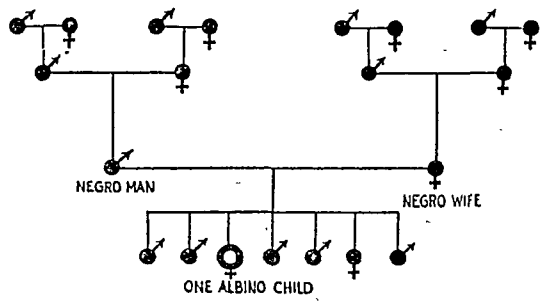

FIG. 2.—Showing genealogy of Family B. The black circles represent negroes and negresses; and the black circle with white centre, an albino.

he was born an albino, his only brother is purely negroid; so far as can be ascertained this brother has no children. His grandparents were pure French on his father's side but pure Malgache of Madagascar on his mother's side. His wife, a negress, is a descendant of a pure negroid stock from Africa. She and her youngest baby appear to be normal in all characteristics.

Family B.—This is a family of nine, being father, mother, and seven children, of whom the third is a pure albino. The entire ancestry consists of pure African negroid stocks, without any albino whatsoever. In this albino child all the typical characteristics seen are similar to those observed in Family A. The parents and other children are normally negroid in all characteristics.

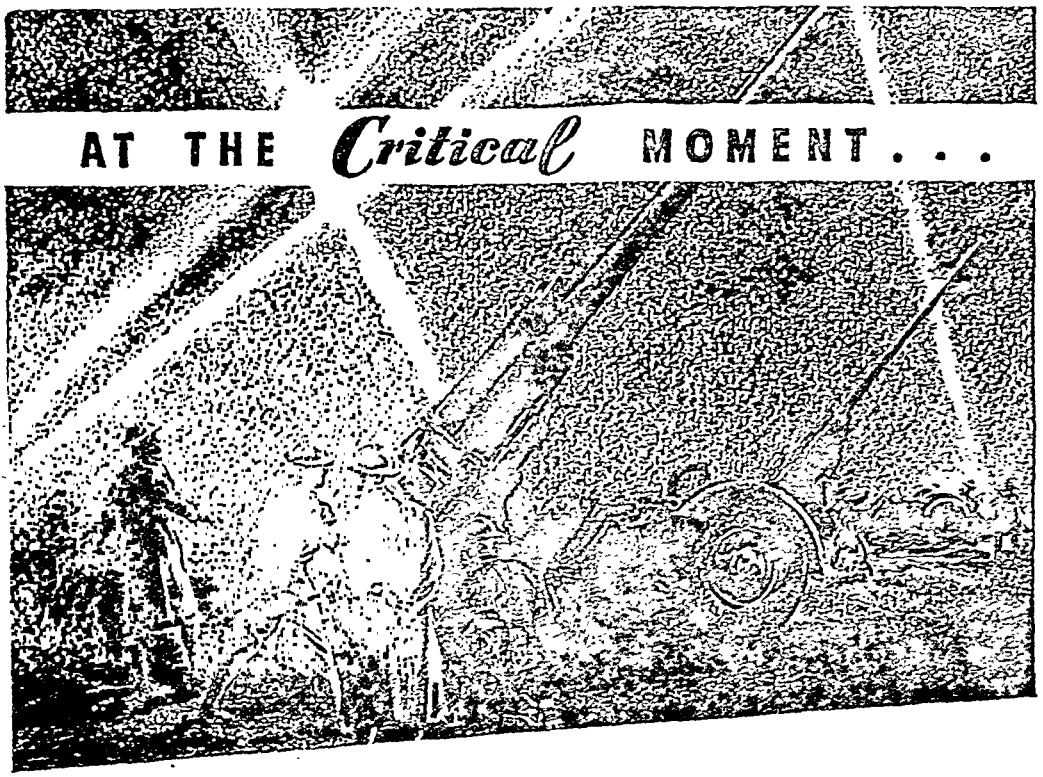
These albinos show certain marked features. There is complete absence of pigment in the skin, the hair, and the eyes. The skin is extremely white, unrelieved by the slightest tint of red from exposure to strong sunlight. The hair is curly, of the negroid type but rather fine, and this is uniformly seen all over the body in all the above cases. The pupil shows a red tint, and the iris surrounding it has a pale rosy colour. Bilateral nystagmus is present in all cases, as also is photophobia. They cannot tolerate strong light, and when asked to face sunlight they close the eyes at once. Myopia, too, is pronounced in these cases, and large letters are discerned to any degree of clarity only at about four to five inches distant. When they are out walking the face and eyes are turned downwards.

Albinism is a congenital anomaly consisting of a remarkable peculiarity in the physical constitution of certain individuals. The Portuguese, who recorded their findings among the negroes of West Africa, called the persons so affected "albinos." The pigment defect has been observed both in the white and in the black races of mankind. It is most common and most pronounced in the negro and Indian races. It has also been encountered in the lower animals, among which are found the white monkey, the albino crow, robin, and opossum, the white hare, and the so-called white elephant, which is regarded with veneration by some Eastern nations.

In these native Seychelles families no mental defect is observed except a slow mental response. The powers of procreation appear to be unaffected. In Family A five albino

FIG. 3.—Family A.

FIG. 4.—Family B.



children are born from an albino father, a condition considered to be of great rarity. In Family B the birth of an albino child to negroid parents seems to be more compatible with the usual observations.

Consanguinity and heredity have been noted among the alleged causes of albinism, but its aetiology is obscure. Can it be due to a fault in the endocrine system, a break or absence of a hormone in the chain which regulates the colouring matter in the skin, hair, and eyes? Is it some defect in the suprarenal gland or in the posterior pituitary gland? In fact, what is it?

THE GREATEST DEVELOPMENT FOR 34 YEARS IN FOCAL ACTINOTHERAPY

Foci of disease in the skin, membranes, and tissues exhibit regenerative healing under topical applications of ultra-violet rays. Developed through thirty-four years of steady progress, this focal application of actinotherapy is now finding much wider use in all branches of practice since this new Kromayer Lamp (the Model V) has been introduced.

The diagrams here reproduced in miniature illustrate the technique of focal actinotherapy as applied, e.g., in leucorrhoea and (below) for hay fever, and show how the shaped quartz applicators facilitate topical application. These are reproduced from the professional handbook "Modern Focal Therapy," a comprehensive review of indications and technique, which will be sent free on request.

The intense little mercury of this new lamp operates EXTRA HIGH PRESSURE in quartz jacket, giving an outp many times greater than earl models. Its water-cooled be of ultra-violet rays produc deep-reaching reactions wh ever applied, and the 2-in quartz window plus ma specially shaped quartz applic tors enable the practitioner apply the radiation on a accessible lesions. The lam starts itself, operates witho variation at any angle, mai tains constant output. power, in design, in control worthy instrument of healing

You are invited to investigate the significance of this new development in your own work. Ask for professiona literature on the indications, technique, and construction of the Kromayer Lamp (Model V), or use the coupon below.

BONE GRAFT SURGERY

Bone Graft Surgery in Disease, Injury and Deformity. By Fred H. Albee, M.D., LL.D., Sc.D., F.A.C.S., F.I.C.S. Assisted by Alexander Kushner, M.D., B.Sc. (Pp. 404; illustrated. 35s. net.) New York and London: D. Appleton-Century Company.

This book is an authoritative and comprehensive exposition of the principles and technique of bone graft surgery embodying the author's technical methods and the experience he has gained in the treatment and follow-up of over 6,000 cases.

In his opening chapter on general principles Dr. Albee lays stress on the complete re-vascularization of the graft by the growth of blood vessels from the host into its Haversian canals which was demonstrated in 1929 in post-mortem specimens specially prepared and injected by Sir Arthur Keith and preserved in the Museum of the Royal College of Surgeons. The author believes that increased blood supply to the diseased tissues via the re-vascularized graft is one of the underlying causes of the beneficial action of the graft in tuberculosis of the spine. From this follows the extreme importance of including all the layers of bone in the graft and of bringing these into as accurate coaptation as possible with the corresponding layers of the host, best accomplished by the inlay graft, which is, generally speaking, the most desirable form of grafting. The author does not approve of either intramedullary or osteo-periosteal grafts. For the latter he substitutes "sliver grafts" which are cut very thin but include all the layers of the donor bone. All graft material that is not autogenous is rightly condemned.

After a chapter devoted to armamentarium, in which he insists upon the necessity for special tools for such specialized work as bone graft surgery and describes his own outfit and specially designed operating table, Dr. Albee passes on to a consideration of spinal fusion, with which his name is particularly associated. This chapter contains a full description of his technique of inlay grafting for spinal tuberculosis, and the text is illuminated by numerous diagrams and line drawings. Dr. Albee is so firm a believer in the benefits of spinal fusion that he performs it for a large variety of spinal conditions besides tuberculosis, for some of which—as, for instance, vertebral eriphysitis and osteochondritis in adolescents—the operation is not commonly performed in this country. In cases of tuberculosis he is a warm advocate of spinal fusion as early as possible in progressive disease in both children and adults. With this, though he makes out a good case in support of his views, he will not meet with universal agreement, especially in this country, where the tendency has always been towards conservatism in the case of children; only specially selected cases are, as a rule, submitted to fusion operation. Even in adult spinal tuberculosis some doubt has recently been cast on the necessity for fusion in every case, notably by Seddon, who analysed carefully a number of cases treated at Stanmore and came to the conclusion that the end-results of cases treated conservatively throughout were no worse than of those treated operatively, and that the time factor was not materially shortened in the latter cases. The unqualified statement, in another part of this chapter, that tuberculosis of the sacro-iliac joint is the most fatal of all joint affections does not accord with experience in this country, and here again Seddon has shown that the results of fusion operations in uncomplicated cases are not superior to those of conservative treatment only. Most surgeons would agree with Dr. Albee in advocating spinal fusion operations in scoliosis, in certain cases of vertebral fracture, and in spondylolisthesis.

In the chapter on hip-joint surgery the author hardly gives sufficient credit to the Smith-Petersen pin in the treatment of fresh fractures of the femoral neck, and few surgeons in this country would agree that the autogenous bone peg is the treatment of choice in these cases, except where open reduction is not considered wise. Nailing these fractures without open reduction is now a firmly established method, and is giving a high percentage of union, failures being due, in most instances, to faulty technique rather than to faulty selection of cases. In cases of non-union, however, the autogenous bone peg is of undoubted value. The important operation of arthrodesis of the hip is fully described, and both here and throughout the book the author, while naturally giving prominence to his own methods, also describes or gives in schematic form alternative techniques designed by other well-known surgeons. His relatively new and important contribution to the treatment of paralytic hip conditions by elongation of the kinesiological lever at the top of the femur is described in this chapter.

In the remaining chapters, on bone graft surgery for ununited fractures, for replacement of bone, plastic bone graft surgery, and arthrodesing and bone block graft operations, the author's mechanical genius has full play, especially in those on ununited fractures and plastic procedures. This is Dr. Albee at his best, and careful study of these clearly described and well-illustrated procedures will certainly repay any surgeon who is interested in this branch of surgery. The book throughout is generously illustrated with radiographic reproductions, and the schemas and line drawings are helpful in clarifying textual descriptions of technical procedures. A full bibliography is appended to each chapter.

PERSONALITY AND INSTINCTS OF ANIMALS

The Personality of Animals. By H. Munro Fox, F.R.S., Professor of Zoology, University of Birmingham. Pelican Books A. 78. (Pp. 124. 6d.) Harmondsworth: Penguin Books, Ltd.

Until comparatively recent times the study of zoology was divided between the morphologist and the field naturalist, who exchanged few contacts. Some twenty to thirty years ago a school of experimental zoology arose which has studied animal life under rigidly controlled scientific conditions. In this entertaining little book, free from the anthropomorphism to which animal lovers are so prone, Prof. Munro Fox has given a popular account of some of the results obtained thereby. We learn that fishes can not only hear but can discriminate between sounds if not less than an octave apart; that a dog's perception of sound includes notes of much higher pitch and is not only ten times as acute as ours but in discriminating the source of a sound is also twice as accurate. We are told that bees can see blue but not red, while they can see ultra-violet rays; hens can see blue but not violet; pigeons can see the red end of the spectrum better than the further end; while cats and dogs are colour-blind. But if animals have poorer colour discrimination than we have, their sense of smell and of position are far more accurate. There is an entertaining chapter entitled "Do Animals Count?" which suggests that the more intelligent ones can count up to five but not beyond, as well as a fascinating description of the way in which a bee's sense of time can be accelerated by thyroid and delayed by quinine. The importance of the hormonal drive in directing instincts is emphasized. Through such information we are skilfully led to realize how differently our world appears to animals. The author reaches the conclusion that those animals

which have fewest instincts possess most personality, for then each individual in its lifetime accumulates a different store of experience on which it acts; each individual is different from its neighbours. Mammals, and more particularly man, have fewest instincts and therefore have the greatest degree of personality.

PHARMACOLOGY AND THERAPEUTICS

Poulsson's Textbook of Pharmacology and Therapeutics. Edited and revised by Stanley Alstead, M.D., M.R.C.P. Third edition, with new appendix. (Pp. 558. 21s. net.) London: William Heinemann (Medical Books) Ltd. 1940.

The third English edition of *Poulsson's Textbook of Pharmacology and Therapeutics* is edited by Dr. Stanley Alstead. It is only two years since the last edition appeared, and the chief change in the present volume is the addition of an appendix which contains an account of the sulphonamide drugs and a summary of the more important monographs in the Second Addendum (1940) to the *British Pharmacopoeia*, 1932.

The publishers state that the exigencies of the time have prevented a complete revision of the text. This is evident in certain sections. For example, the vitamins are dealt with in little more than a page, and the text suggests that the chemical constitutions of most members of this group are still unknown. We found no mention of vitamin K. The sex hormones occupy only half a page, and no mention is made of the existence of synthetic oestrogens. In the chapter on the thyroid the isolation of thyroxine by Kendall is mentioned but no account is given of the subsequent work on the chemistry of thyroxine. These examples could be multiplied, and we feel it necessary to mention them because the textbook is intended for use by students, and a student who relied upon it for information concerning certain recent pharmacological advances might find himself in difficulties in an examination.

STATISTICAL CALCULATIONS

Statistical Calculation for Beginners. By E. G. Chambers, M.A., Assistant Director of Research in Industrial Psychology, Cambridge; Fellow of the Royal Statistical Society. (Pp. 110. 7s. 6d. net.) Cambridge: The University Press. 1940.

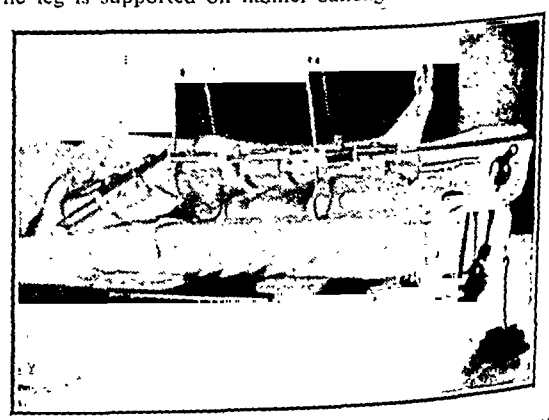
The object of Mr. Chambers in writing this book was to provide field and laboratory workers, especially those doing psychological work, with explicit instructions as to the calculation of the various statistical indices necessary to describe their results, interpret them, and measure their significance. Mr. Chambers has, we think, succeeded; any docile and industrious student who obeys the instructions will reach precise results. Whether a perusal of the book is likely to fire an ordinary reader's enthusiasm for statistical research is another matter. Mr. Chambers has perhaps kept a little too strictly to the terms of reference he gave himself. It is true that proofs of the methods the arithmetic of which he describes are (as he says with a rather irritating frequency) often difficult. It is equally true that the principles involved can usually be explained without mathematical symbolism. To take a simple example, to *prove* that the limit of the binomial distribution of "heads and tails" is a "normal" curve is a rather difficult piece of algebra. But any intelligent person with a pencil and piece of paper can convince himself, by trying out the possibilities of 2, 3, 4, 5, or more tosses, that the graph *does* become smoother and smoother, and will be more willing to take on trust the proof that the "curve" to which he is gradually approximating has such or such an "equation."

The student will find the manual of much practical use if he first reads, fairly quickly, some general book on statistical principles.

Notes on Books

The American Gynecological Society was founded in the year 1876, and the sixty-fifth volume of its *Transactions*, edited by Dr. Richard W. Te Linde, has been published at St. Louis by the C. V. Mosby Company. This comprises the presidential address delivered by Dr. Fred L. Adair, and seventeen papers reprinted from the *American Journal of Obstetrics and Gynecology* with reports of the discussions that followed them. Three of the papers are on obstetrical subjects, the remainder being gynaecological. The papers and reports are preceded by official information, and followed by five memorial notices of deceased Fellows. The British Honorary Fellows of the American Gynecological Society are, in order of their election, Herbert R. Spencer, J. Munro Kerr, T. Watts Eden, W. Fletcher Shaw, Victor Bonney, and Eardley Holland; and the names of seventeen of their fellow-countrymen are recorded in the list of deceased Honorary Fellows.

The second edition of Dr. E. E. CLAXTON'S clear and useful book on weight reduction contains very few alterations, but a war appendix has been added, consisting of two pages only, on vitamins. May the day soon come when this book will be wanted again, because in the meantime war conditions provide all the weight reduction needed in most cases. Its full title is *Weight Reduction: Diet and Dishes. With Tables and Recipes Suitable for Diabetics;* the publishers are William Heinemann (Medical Books) Ltd., and the price is 8s. 6d.



Preparations and Appliances

A THOMAS SPLINT MODIFIED TO BRAUN'S TYPE

Mr. J. C. R. HINDENACH, M.D.N.Z., F.R.C.S., writes:

Those of us who had to shift at a few days' notice from a well-equipped London hospital to a sector hospital stocked from Government stores have often bemoaned the lack of appliances to which we had been accustomed. Among others, Braun's splint, so useful in the treatment of certain fractures of the tibia, was not supplied. However, the Government issues of a Thomas splint, two footpieces, and a bed-pulley and clamp can be, to some extent, adjusted to make up for this loss. The photograph is almost self-explanatory.

A Thomas splint, with padded ring, is bent at the knee. The leg is supported on flannel bandages held with clips and

safety-pins. Extension is obtained through skin strapping or a Kirschner wire through the os calcis or lower end of the tibia. Support to the splint is given by using two footpieces suitably spaced along its length. These should rest on a board in the bed. Fracture boards are placed under the distal half of the mattress, enabling the ring of the splint to sink into the bed. If this does not occur the lower half of the ring will tilt the splint. If the footpieces are reversed to overcome this and raise the splint it is found that the pulley-clamp at the end of the bed cannot be lengthened and the traction pull will not then be horizontal.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY APRIL 12 1941

MEDICAL MAN-POWER

ıe needs of the fighting Services, of the expanding ır industries, and of agriculture are being met by the ıbsorption of men and women who have abandoned craft in which they had acquired skill and by what called dilution. In the economic ups and downs of ıde men and women pass from one occupation to ıother in which they can make a better living, so that ere is some reserve of workers with experience in a ırticular industry who are not employed in it at any ıe time. It is augmented by a very large number of ıined women who have married and ceased to follow eir premarital occupation. All these can be, and e being, drawn upon for the wartime reorganization industry. Some of them require re-education, but is in connexion with dilution that intensive training imperative as a substitute for the usual long apprenceship to a craft. The nursing profession, in which ıortage had become acute before the war, has been ıbjected to both these processes, non-registered nurses eing supplemented by assistant nurses and nursing ıxiliaries who have been given a brief course of train-ıg, while many fully or partially trained married ırses have returned to the service in a whole-time r part-time capacity for the duration of the war. heir salaries and conditions of service are being imroved in order to accelerate these processes.

The position in the medical profession is differnt. Men rarely leave it for other walks of life. ome retire with advancing age. Many medical omen continue to practise after marriage. The eserves are therefore small. Both men and women ho had given up the practice of medicine for the bove or for other reasons have returned, but their ıumbers are insufficient to ease the situation greatly.)n the other hand the possibilities of dilution in a proession which requires so long and arduous a training re limited, though they do exist. The large drain on nedical personnel created by the essential demands of he fighting Services has therefore to be balanced mainly)y those left in civil practice bearing a heavier burden. t was to consider this situation that the Robinson Committee was appointed last December at the urgent equest of the Central Medical War Committee, and ı recent circular of the Ministry of Health to local ıuthorities and voluntary hospitals may be regarded ıs the first patent response to its recommendations.[1] The calls of the Services have been great, and it is good to know that they are now reviewing their medical establishments so as to reduce them as far as possible. The Ministry of Health is also reconsidering the staff engaged in the Emergency Medical Service with a view to its reduction and replacement to some extent by foreign practitioners. Similar action is urged upon civil hospital managers, the suggestion being made, for instance, that where two Class A and two Class B2 officers are engaged in a hospital the number might be reduced to one or two of Class A and one Class B2 without serious loss of efficiency. They, too, are asked to give favourable consideration to the replacement of a certain number of British practitioners by those of foreign nationality. An important suggestion is that the resident staffs of hospitals should be pooled to a certain extent, presumably within a hospital region, so that hospitals which cannot in present circumstances be staffed up to the optimum standard may obtain temporary relief at times of stress from others less embarrassed. The Ministry further indicates that the time has now come to release junior house officers by replacing them with senior students in their final year of study, as in the last war. They should, however, be employed only in hospitals where they remain under supervision by members of the teaching staffs of their medical schools. They should usually be appointed for three months only and should constitute not more than 50% of the resident staff. For the purposes of the Emergency Hospital Scheme salaries will be recognized at the rate of £50 a year, with board and lodging (not exceeding in value £100 a year). As regards the medical staffs of health departments who are not engaged in hospital duties, the Ministry urges the maximum of economy without prejudice to essential services. Women, for instance, may well replace men engaged in maternity and child welfare work, and part-time assistance by general practitioners over military age who can afford time from their private practices might be utilized to release young whole-time medical officers. Economy in the use of administrative medical officers may be effected by combining areas and relieving medical men so employed of work of an administrative and clerical nature which could quite well be done by lay officers.

If these proposals are energetically taken up by the several responsible bodies they should do something to relieve the present situation, although they might very well have come sooner. The excellent suggestion to employ medical students in hospitals, for instance, has reached hospitals and medical schools at a time when final-year students are nearing their examinations and are therefore most likely to be thrown out of their academic stride if they devote themselves assiduously to the new routine hospital duties to which they will be suddenly called. Fortunately some medical schools, notably Liverpool, have already moved far in this direction of their own volition. The effect of this and the other proposals will depend largely on the appreciation by all concerned of the fact that services of any kind cannot be staffed at an optimum level at the present time. Above all, the action taken as to their establishments by the fighting Services will be awaited with interest and some anxiety. It is their great demand that has created the difficulties in the medical profession, which was not overstocked before the war, and something more than their own assurance is required to convince us that they are approaching reorganization of their medical staffs with a realization of the shortage in civil life. To a certain extent the same comment applies to emergency and other civil

[1] Ministry of Health. Circular 2323, March 28, 1941. See this week's *Supplement*.

hospitals, and the public health service. It is perhaps natural that senior medical officers and honorary staffs should be reluctant to release house officers who appear to them to be essential to the efficient performance of both the emergency duties cast upon them and also their ordinary civilian work. But the effect so far has been to deplete general practice disproportionately. The crux of the situation is contained in these sentences of the circular: "Private practice has already been seriously affected by the recruitment of practitioners of military age, and if a fair balance is to be preserved and essential medical services carried on, other branches of medical practice ought to make further contributions to the Armed Forces." As final comment it may be repeated that the Armed Forces themselves can also make a contribution to the solution of this complex problem.

PROBLEMS IN WOUND HEALING

The healing of wounds was considered at a recent meeting of the Medical Society of London, and an account of the discussion appears at page 568. The time is opportune for a brief survey of this important question. The surgeon's work rests upon the fundamental assumption that wounds will heal provided certain relatively simple conditions are fulfilled. This inherent tendency to healing and repair is so marked a characteristic of damaged living tissue that it has led to a comparative neglect of many of the underlying and determining biological factors. The wounds may be accidental or surgical, clean or infected; they may be wounds of civil life or wounds of warfare. Yet in the absence of some overwhelming disaster such as serious shock, haemorrhage, or infection, Nature can be relied upon to make the most strenuous efforts to repair these breaches of her tissues however they have been inflicted. And if, in Pirogoff's words, we consider war as a "traumatic epidemic," and under modern conditions an epidemic that knows no frontiers, then a time of war must be a special one for the study of the problems of wound healing. Why then has the subject been so neglected? First, because the whole of surgical technique assumes the potentialities of wound healing, as in the absence of these all surgery would be impossible. Secondly, the more detailed study of wound healing has been dependent on a whole host of ancillary developments all having some bearing upon the processes of tissue repair: on surgical technique, asepsis, and bacteriology; on the effects of various suture and ligature materials in wounds; on biochemistry and the knowledge of specific growth stimulants; and finally on the ramifications of the more recent knowledge of nutrition. The advances in all these directions have done, and are still doing, much to elucidate the mysteries of wound healing. The words of Ambroise Paré are as true to-day as when he used them to conclude his case records, "I dressed him and God healed him." The greater our knowledge of the processes of wound healing, the greater the need for the surgeon to see the therapeutic implications of this knowledge. The patient must be made safe not only for the actual operation but also for the whole course of repair of his injury.

The subject may be approached by many ways, but all lead in the same direction. In war it is inevitable that the question of infection should be uppermost in our minds and therefore claim our first consideration. Infection is the greatest enemy of wound healing. But although we know that the elimination of bacterial infection is the first step in securing the healing of a wound, infected wounds do not always provide the best material for the study of those factors which promote healing. These wounds are such complicated battlegrounds between offence and defence, between destructive and reparative forces, that they make difficult any detailed analysis of the various elements in repair processes. On the other hand, the conclusions drawn from a study of experimental wounds in animals cannot always be directly applied to human beings. But in addition to these two types of wounds there are those produced by the surgeon in an attempt to rid the body of some disease process, and a study of these may go far to illuminate the processes of repair.

Much of the more recent work on wound healing has come from America, and much of it has been concerned with biochemical and nutritional aspects. At the same time much has been learnt from the failures of normal wound healing, from the cases in which for one reason or another the expected results have not been achieved. The conditions which lead to failure in wound healing may thus indirectly shed much light on the conditions which are the prerequisites of success. Whipple[1] has recently reviewed the whole subject, especially from the standpoint of the lag or latent period in the development of healing. His work shows that wound healing is an orderly biological process which conforms in general to the laws of growth. In the individual wound the three most important processes are the amoeboid movement of cells, their mitotic proliferation, and the maturation of cells engaged in the fusion of wound surfaces. The local factors which determine the reparative processes depend upon the amount of damaged tissue in the wound, the vascularity and the integrity of the blood supply to the damaged tissues, the nature of the exudate in the wound space and adjacent tissues, the number and character of the local infecting organisms, and the number and character of the local foreign bodies to be encapsuled or extruded. But these purely local conditions are far from being the only ones of import. The more general factors include the age of the tissue (whether adolescent, adult, or senescent), the state of hydration, the state of nutrition (especially in relation to protein and to antecedent loss of weight), the vitamin balance, and the state of the general circulation and the blood. Orderly and normal wound healing is thus dependent upon a close interrelationship between local and systemic factors. Experiment has confirmed the view of experience that age is a factor of great significance. Experiment has demonstrated that departures from the normal electrolytic and protein balance delay the processes of healing. Vitamin C is now known to play an important part in the formation of collagen fibres in wounds, and vitamin K in the production of prothrombin and so in the control of haemorrhage. Circulatory efficiency and the state

[1] *Ann. Surg.*, 1940, 112, 481.

of the blood may determine not only the immediate outcome of the operation but also the speed of the repair processes.

The subject of wound healing may also be looked at in another way. What, for example, are the conditions that determine the breakdown or dehiscence of surgical wounds which might be expected to heal by first intention? Sokolov[2] has reviewed and analysed the factors in the disruption of abdominal wounds in 732 cases. This phenomenon was twice as common in men as in women, and commoner in the first half of the year than in the second (this was thought to be due to a lowering of the vitamin C content of the tissues); it occurred especially between the ages of 40 and 60, in association with emaciation, in the presence of malignant disease, or in association with operations on the stomach or intestinal tract; and, finally, the wounds which broke down were usually not infected. The figures quoted by Sokolov revealed that wound disruption took place in 2 to 3% of all abdominal cases. Other workers have arrived at similar results and conclusions, and all have stressed the fact that failure of the healing process is most likely to arise in patients suffering from gastro-intestinal disease. In reporting the post-mortem findings in a series of cases after partial gastrectomy Payne[3] stressed the fact that in a considerable proportion of these the fatal outcome was associated with an almost complete lack of response at the site of the anastomosis. Studley[4] has also shown that the mortality in operations for peptic ulceration is directly proportional to the antecedent loss of weight. The general nutrition of the surgical patient is thus inseparably bound up not only with the immediate prognosis of the operation but also with the breakdown or dehiscence of the operative wounds, whether visceral or parietal.

During recent years much work has been done on vitamin C in relation to the healing of wounds. Lanman and Ingalls[5] demonstrated the importance of this in securing normal repair of experimental wounds in guinea-pigs, an observation that has now been confirmed and amplified in a recent paper by Hunt.[6] These experimental studies show that collagen does not form in the healing wounds of guinea-pigs partially deficient in vitamin C; the proliferating mesodermal cells fail to mature, and the healing of the whole wound is profoundly disturbed. In a series of twenty-eight human cases investigated post mortem and reported by Hunt there was a comparable histological picture in eight, and in five there was disruption of the abdominal wound, and in three leakage at the gastro-intestinal suture line. It seems clear, therefore, that a subscurvy state leads to a gross disorganization of the whole orderly process of wound healing, and supports the view that the same deficiency may lead to failure of wound healing or even to wound disruption in human beings after surgical operations. This work has recently been confirmed by Fox[7] in a paper on experimental human scurvy.

The general nutritional state of the surgical patient is of course only one aspect of the problem of wound healing, but it is one which in this country has been largely neglected. Clinical and laboratory evidence, however, both show that in the presence of important nutritional defects the normal sequence of events in healing does not take place, that the processes of repair may be seriously delayed or retarded, that the risks of complications from the non-healing of visceral surfaces are greatly increased, and that breakdown of a wound is likely to happen. And for every wound in which there is some serious departure from normal healing there are probably many more in which some minor disturbance occurs and may prolong the patient's stay in hospital and retard his ultimate recovery. Behind every wound there is the nutritional state of the individual patient against which all the reparative processes of Nature must operate. A nutritional disturbance may result from the patient's disease or be independent of it; it may be directly due to some gastro-intestinal lesion; or the lesion may reside in a background of poor wages, inadequate food, bad housing, or ignorance of personal hygiene. It is not difficult to remember that a surgical wound will not heal in the presence of a foreign body, but it is easy to overlook the fact that delays in healing, or even non-healing or disruption, may perhaps be due to years of poverty and malnutrition.

The surgeon, in fact, must look beyond the neat incision he makes in the patient's flesh to the social and economic position of the patient as a human being. He might well, too, look more closely into the question of hospital dietary. Tradition and the steward still so often combine to provide the patient with a diet that has little to recommend it apart from its calorie content. Every surgical patient presents an individual nutritional problem, and the help of the expert dietitian should be the rule and not the exception. A serious burn or a major abdominal or other operation is as much an acute nutritional problem as the management of diabetes is a chronic problem. To heal the burn or to repair the damage after the surgical operation will require first-class building materials, without which local dressings and careful surgical technique will be of little avail.

MODERN TROGLODYTISM

Those who sleep in their beds in vulnerable areas are apt to view a little superciliously that large section of the community—now 60,000 in the London Tubes alone (it was three times as numerous last September)—who nightly, air raid or no air raid, seek communal shelter and go to their bunks with the same air of rightful occupation as hotel guests go to their rooms. Lord Horder, in his address to the Royal Society of Arts on April 2, made a chivalrous defence of the modern troglodyte. He said that it was one of his regrets that in "this shelter business" there had been no time to make an extensive census on psychological lines in some of the large shelters, not merely to show where the people came from but exactly why they were there. Some were there because they had been bombed out of their homes, some because their homes were not protected, but there were many others who, for one reason or another, were unable to stand up to the terror of the "blitz" and the noise

incident to it. No priggishness should enter into this matter. After all, most of these people worked by day, and sleep was essential to all work. Many comments had been made on the queer places and attitudes in which these folk got their sleep, and upon their patience and good humour in beastly surroundings. But did it all mean that there was only too little difference between their nights in the large public shelters and their nights in their own homes? It was a terrible indictment of the social system that the shelter conditions which it had now been possible to establish should represent for these fellow-citizens of ours something better and happier than they had known before. That it should have needed a war and life underground for half the twenty-four hours to achieve a result which was bringing joy to the hearts of social workers was a humiliating thought. One other good thing was emerging from this experience. The mood of these shelterers was extremely plastic, so that among them there was a field for health education the like of which had never existed before. They had, and they appreciated, their medical aid. Mothers submitted to the shelter doctor's persuasive argument about diphtheria immunization when a visit to the clinic for this purpose would never have been made. The nurse was listened to with attention, and her ministrations gratefully received. Here was field work of the best kind in preventive medicine. Lord Horder also commented on the obstinate good health of the shelter population, and indeed of the whole community both above and below ground. The situation which arose last September seemed to be full of alarming hygienic hazards. There was gross overcrowding, and it was at that time nobody's job so to condition these places as to make them fit for habitation. The onus was eventually accepted by the local authorities—and Lord Horder paid a tribute to the borough medical officers of health, who had been key men in the situation throughout—but there was a tiresome lag before the recommendations of the advisory committee were carried into effect. Yet the anticipated epidemics and illnesses did not arrive. Even lice and bugs had been difficult to find. In the country as a whole there had been only as much diphtheria as the people deserved, seeing that they would not have their children immunized; the usual seasonal outbreak of measles had not been of a virulent kind; the influenza curve had reached a level which could hardly be dignified as epidemic; only cerebrospinal fever had shown an increase, but the figure was not alarming. Public authorities were puzzled to find the reason for the robustness of the public health. He had even heard that a small committee was being formed to inquire into it. Was it due to a better state of nutrition, or to greater dispersal of the population, or, where shelterers were concerned, to the fact that many of them had been living under better conditions than in their own homes, with more fresh air, less heated atmospheres, and more regular exercise? There were, of course, unknown elements in the very determination of epidemics, and the causes of a rise or fall in the virulence of a bacterium or a virus were unknown to us. But, however it might be, "shelter disease" as such had not appeared. Dr. W. A. Daley, medical officer of health to the London County Council, who presided at Lord Horder's lecture, said that in London during the first three months of 1940 there were 4,393 deaths from influenza, pneumonia, and bronchitis, and in the corresponding period of this year only 3,089, and even allowing for the decreased child population of London the cases of scarlet fever and measles had been relatively few. But the danger was still there, the good fortune experienced during a winter past could not be predicted of a winter to come, and vigilance must be sustained.

DERMATOMYOSITIS

This rare and interesting disease has been recognized for a good many years. It is characterized by hardening and atrophy of the muscles, and the skin is always affected to some degree, either by an eruption resembling lupus erythematosus or by the development of thickened and hardened areas of integument closely resembling scleroderma. Most of the workers who described the earlier recorded cases insisted on the necessity for and difficulty of diagnosing it from sclerodermia, but at a discussion held on it at the last annual meeting of the British Association of Dermatology considerable support was forthcoming for the view that dermatomyositis and sclerodermia are really the same disease, although they must both be differentiated from poikilodermia atrophicans. Furthermore, a good deal of evidence was brought forward to show that the condition is intimately associated with thyrotoxicosis. The question was attacked from clinical, histological, and biochemical aspects. Dowling pointed out that in every case of dermatomyositis superficial sclerodermatous changes are seen, and he also drew attention to the striking similarity in the course of the two conditions. He is by no means the first observer to attempt to establish the identity of dermatomyositis with sclerodermia, for Oppenheim did so as long ago as 1903. Since then much evidence has been collected in support of his proposition. The relation between this disease and thyrotoxicosis has been emphasized too, but much more recently. The evidence in its favour is partly histological and partly biochemical. One of the most important points is the occurrence of "lymphorrhages" (which are collections of lymph cells) in the muscles both in sclerodermia and in thyrotoxicosis, while in all the recorded necropsies on cases of generalized sclerodermia pathological changes have been found in the thyroid. Fuller details on the histopathological similarities will be found in Freudenthal's paper read at the same meeting, while Griffiths, in discussing the biochemical side of the problem, pointed out that in both conditions creatinuria is well marked. The significance of this symptom seems to be that it is indicative of diminished muscular strength, and it may be associated with loss of power to form glycogen. That this may be so is indicated by the fact that in dermatomyositis less sugar is removed from the blood under the influence of insulin than is the case normally. Still another point of similarity is the occasional occurrence of decalcification of the bones in both conditions, though there is no alteration in the blood calcium or inorganic phosphorus. Our knowledge of metabolism in dermatomyositis is still very imperfect, but we can at least say that the disturbances met with are strikingly similar to those seen in diseases which we know to be of endocrine origin, especially thyrotoxicosis.

GENETICS OF THE HEREDITARY ATAXIAS AND SPASTIC PARAPLEGIA

A few months ago we published[1] an annotation on Dr. Julia Bell's fine monograph[2] on the hereditary ataxias and spastic paraplegia. The monograph covered the literature in great detail, presenting 273 family histories in which more than one case appeared in a family group. In addition, there was a personal collection of forty-six unselected cases, made with the help of Dr. E. A. Carmichael. The relatively brief analysis of the data contained much of neurological and genetical interest, but did not pretend to be exhaustive; actually the results of a more detailed

[1] *British Medical Journal*, 1940, 2, 160.
[2] *Treasury of Human Inheritance*, 1939, 4 (Part III).

examination were promised for the future. An analysis has now been published by Prof. Haldane,[1] and a remarkable discovery has been made: that recessive spastic paraplegia is due to a partially sex-linked gene (which may exist in several allelomorphic forms). Haldane's discovery of partial sex-linkage[2] was a major event in the history of human genetics. Briefly, having satisfied himself by the histological evidence that the X- and Y-chromosomes of man contain a homologous portion which exhibits crossing over, he made a search for corresponding genetic manifestations. In a very short space of time he found three instances in which the evidence for this mode of transmission was very strong (xeroderma pigmentosum, complete colour-blindness, recessive retinitis pigmentosa unaccompanied by deafness), and three in which the evidence was less strong though still good (some cases of dominant retinitis pigmentosa, Oguchi's disease—a form of night-blindness—and recessive, severe epidermolysis bullosa). Unlike the case of ordinary sex-linked inheritance, as in haemophilia, in which the pedigree is striking and highly characteristic, partially sex-linked pedigrees do not differ at all obviously from those of ordinary dominant and recessive cases: and it is unlikely that this mode of transmission would have been discovered without a deliberate search. In essence, a man who has received such a gene from his mother transmits it to more than half his daughters and less than half his sons; the proportions are reversed if he received it from his father. In her monograph Dr. Bell tended to the hypothesis that a genetic unity underlay the group of diseases in question—that is, that one main gene might usually be responsible and that variations between family groups might be due to modifying factors. Haldane's findings do not support this hypothesis (we expressed the same view in our annotation). As already mentioned, the recessive cases of spastic paraplegia show partially sex-linked inheritance, while the dominant cases do not. It is true that there is some evidence of this mode of transmission in the case of Friedreich's ataxia and spastic ataxia, but it can account for a small fraction of cases only. One of Dr. Bell's striking findings was the very strong tendency for members of the same family group to display a characteristic age at onset of the disease. Haldane shows that this cannot be attributed to modifying factors, and that there must be at least three different recessive, sex-linked genes causing spastic paraplegia. He further concludes that it is highly probable that they are allelomorphic—that is, situated at the same locus on the sex-chromosome pair. Many cases are known in plants and animals in which the members of such a series of genes may be presumed to act with different degrees of intensity, and he has himself pointed out a probable instance in man in the case of haemophilia.

LEARNING TO WALK

Several studies of the normal development of the child have already been made by Dr. Myrtle McGraw of New York, and in a recent communication[3] she describes the neuromuscular development of the infant as it learns to walk. She points out that in order to walk independently the child must (*a*) maintain balance in an erect position, and (*b*) propel the body forward by alternate movements of the lower extremities. She first studied the propulsive movements which the child makes before it begins to control balance. Analysing 3,387 observations made on eighty-two children ranging in age from birth to 8 years (two-thirds of the observations were recorded on cinematograph films), she chose seven progressive phases. The first is the "newborn or reflex stepping phase," in which the infant, held under the arms, is in a position of general flexion and frequently makes rhythmical stepping movements. Within a few months comes the "inhibitory or static" phase: the child begins to hold its head more steadily in line with its body, or even extended, and the tendency to reflex stepping is more or less suppressed or inhibited. At the age of about 250 days most children pass into a "transition phase," in which the child moves its body up and down holding its feet still, or, alternatively, stands still and thumps first one foot and then the other up and down. Next comes the "deliberate stepping phase," reached generally by the end of the first year of life, and then the "independent stepping phase," which was attained satisfactorily in 425 days by 77% of the children under observation. The two last phases—namely, "heel-toe progression," and the "integrated or natural phase of erect locomotion," which is characterized by a swinging of the arms in association with movements of the opposite lower extremity—are reached at more indefinite periods. The author shows how these phases support the theory that at birth the infracortical or nuclear portions of the nervous system are dominant, and that later there is a gradual assumption of activity by the cortical levels, a theory which has the support of certain histological studies. Dr. McGraw completes her investigation with a study of the child's attempts to get into an upright position. Here again seven phases were chosen from a mass of detailed data. Phase 1 is essentially passive: if a newborn infant is pulled into a sitting angle and an effort is made to pull it upward there is no co-operative response. After a few months the child shows an incipient urge to push itself upward after it has been pulled into a sitting position; this is the "extensor thrust phase." Next comes the "orthotonic phase," when the child places its feet on the underlying surface and, as it is pulled upwards, extends its lower extremities and attains something of an erect position. In most infants this is reached at about six months, and is followed very shortly by "the vertical posture phase," in which the child will push itself into a leaning position on its feet and then get upright as it brings the shoulder girdle over the pelvic girdle. In the next or "vertical push phase" it begins satisfactorily to co-ordinate the movements of the preceding phase; it pulls itself up by the bars of its cot or some other support, at the same time pushing with its legs. The child, now nearly a year old, has reached "the independent rising phase," in which its movements are a roll from the supine to a prone position and an initial push up with the arms. In the final or "integrated phase" it gets up by way of the sitting position, the complicated succession of movements appearing as one action. Dr. McGraw's detailed studies are not easily reduced to a few lines of description and they suffer in consequence, but those who are interested in this subject will find much of interest in the original article.

At the statutory Comitia of the Royal College of Physicians of London held on Monday, April 7, Sir Charles Wilson was elected President in succession to Sir Robert Hutchison, Bt.

The Central Midwives Board has unanimously re-elected Sir Comyns Berkeley as its Chairman for the year ending March 31, 1942.

SOME AIR-RAID CASUALTY EXPERIENCE

BY

A. M. M. PAYNE, M.B., B.Ch.

Medical Officer, Emergency Medical Service

It may be useful to record the work of a casualty clearing station from the point of view of the organizer who is primarily concerned with the smooth running of the hospital and with the provision of facilities for treatment.

Analysis of Cases

In four months 226 air-raid casualties were admitted to the hospital. This number is not large, and if the cases had been evenly distributed throughout the period they could have been dealt with by the normal hospital services. Casualties were received on thirty-two occasions, on only seven of which were the numbers large. The remaining twenty-five occasions contributed a total of 72 cases, the highest individual number being 8. The normal hospital service could have dealt with these. On seven occasions a total of 154 cases were admitted—five times at night, comprising 24, 18, 17, 16, and 13 cases, and twice by day, comprising 38 and 28 cases. It is on these occasions that the organization is tested, since the cases all arrive within a short time, the majority in less than half an hour.

In order to give some idea of their degree of severity the cases may be classified into six groups:

Group I.—Hopeless cases. Multiple open fractures, gross head injuries, and extensive abdominal wounds, with impalpable pulse and unregistrable blood pressure. These patients all died within an hour of admission.

Group II.—Severe injuries requiring resuscitation before operation. Multiple lacerations and open fractures with moderate or severe shock.

Group III.—Severe injuries requiring immediate or early operation. Abdominal perforation and haemorrhage. Shock is usual, but the injury takes precedence.

Group IV.—Moderately severe injuries with little or no shock. Lacerations and fractures with normal blood pressure. Early operation would be safe in these cases, or they could stand some delay.

Group V.—Minor injuries. Abrasions and smaller lacerations without shock, or some shock with little or no injury. Most of these cases could be discharged in a day or two.

Group VI.—Trivial cases which could be discharged instantly if necessary.

The numbers in the various groups were: Group I, 9; II, 38; III, 5; IV, 87; V, 45; VI, 42. On the seven occasions on which larger numbers were received the totals were respectively 8, 31, 4, 59, 30, and 22: as will be noticed, the proportion of serious injuries is higher.

The number of cases taken to the operating theatre was 131, and the operations performed fall into five groups:

1. Orthopaedic, including amputations	61
2. Excision and débridement, including burns ..	60
3. Abdominal perforations	5
4. Head surgery. Depressions or penetrations ..	3
5. Chest wounds	2

The total number of deaths was 33, excluding persons brought in dead, these not being counted in any of the above figures. Eleven patients died after operation; the remainder never recovered sufficiently to be taken to the theatre.

It has been interesting to observe that the incidence of severe injuries is higher in the open than in shelter. Three groups of casualties occurring out of doors comprised 83 cases: Group I, 7; II, 25; III, 4; IV, 36; V, 10; VI, 1. Three groups of casualties sustained indoors totalled 53: Group I, 0; II, 5; III, 0; IV, 13; V, 15; VI, 20. Casualties incurred in the open included a number of cases of compound comminuted fractures of the limbs and penetrating wounds caused by bomb fragments. We have not yet observed any "blast effects." Casualties occurring in houses comprised lacerations, contusions, and fractures, the majority closed, but a few open. Glass produced many bad injuries. A piece was driven into the skull of one man; there have been several cases of damage to the eyes, and a number of severe lacerations of the face.

The general principle that the basement is the safest place seems to be confirmed: unfortunately there may have been many persons trapped in the basements and fatally injured who are not brought to hospital.

First Aid

The first aid rendered before admission to hospital has on the whole been good. There have been two main faults:

1. *Tourniquets.*—These are often applied, but are hardly ever necessary. Stretcher parties should be taught that a tourniquet is to stop bleeding, and that if there is no bleeding, however serious the injury, a tourniquet is not required. The mere fact that there is blood around an injury is not an indication for a tourniquet. In addition, when a tourniquet has been applied it has nearly always been just tight enough to stop the venous return without controlling the arterial bleeding. In effect it was actually increasing fluid loss.

2. *Splints.*—Too many fractures have been brought in unsplinted. The result is great pain to the patient when being moved and an inevitable increase in shock, quite apart from the danger of adding to the local damage. The advantage of splinting is well worth five minutes' delay in bringing the case to hospital. If stretcher parties have not enough splints more should be provided.

I suggest that immediately an incident has occurred causing more than one or two casualties a doctor should be sent to the scene. He could be obtained from the nearest Emergency Medical Service hospital. He would be able to supervise the first aid, especially the points referred to above, and, perhaps even more important, he could give morphine on the spot. Patients have been brought in screaming with the pain of being moved. It may well be that early morphine is as important as warmth to the badly injured. In addition he might be able to send some of the Group V and all Group VI cases to a first-aid post instead of to a casualty clearing hospital.

Transport and Casualty Reception

Each ambulance contains four stretchers. It is most convenient to unload these on to wheeled trolleys and replace with spare blankets and stretchers. There should be at least four trolleys and ten stretcher-bearers—two per trolley and two unloading. It is useful to have two extra bearers in the reception ward to help in lifting the patient on to the bed. Inside the hospital, cases are being taken to the theatres and the wards. As a rule reception is slowing down by the time cases are ready for removal, so that the unloaders can assist. There should be at least three more pairs for transport inside the hospital. It is useful to place canvas stretchers with detachable poles on the reception beds in order to minimize the pain of lifting. Even if this is done all fractures should be splinted before moving. Thomas's knee-splint is most convenient for the lower limb.

It was found early on that the cases should be moved as little as possible and that it was often impossible to assess the severity of the injuries without a complete examination, including the removal of clothing. The patients almost without exception were very brave and would often make light of their injuries, so that it was difficult to find out by questioning where they were injured. A frequent reply was, "Only scratches." "Go and look after someone worse hurt than me." Often the "scratches" turned out to be important injuries. As a result any attempt at preliminary sorting was abandoned and all cases were admitted direct to a reception ward of twenty beds, where they were given heat from an electric cradle as a routine. A reserve ward of twenty beds was similarly equipped. The first inspection is a rapid preliminary round by the registrar or resident medical officer on duty. Morphine and A.T.S. are prescribed, the clothes removed, and the wounds inspected for haemorrhage. All wounds are covered with clean towels to prevent further contamination. The surgeon and physician on duty make a full examination of each case, notes are taken, and intravenous therapy ordered as necessary.

Procedure in Hospital

Transfusions.—Transfusions must be begun as soon as possible. There should be at least six medical officers prepared to start them, and even then all cases may not be dealt with for over an hour. Transfusions on shocked patients are often very difficult, and the assistance of doctors practised in intravenous work is essential. Junior residents will not infrequently be unable to locate a vein through the skin, and cutting down should be done as a routine unless a highly skilled practitioner is present. Completely equipped trolleys, proper lighting, and adequate support for the arm must be provided in each case. We have found cannulae easier to work with than the needle supplied with the Government equipment.

Blood Pressure.—It is of the utmost importance that regular blood-pressure and pulse readings should be kept. One person should be made responsible for this or readings may be missed. The blood-pressure reading has proved the best guide to the patient's condition. An additional supply of sphygmomanometer cuffs that may be left on the patient's arm saves much trouble.

Operation List.—The preparation of an operation list is important and difficult. It cannot be done at once. All that can be achieved until the effects of treatment are noted is the classification of cases as "early," "for resuscitation," or "when convenient." The condition of the patients must be constantly reviewed by someone in close touch with the theatre, preferably a senior surgeon. This is perhaps the most responsible work of all, since so much depends on operating at the optimum time. It should be noted that operations on Group II cases cannot as a rule begin before three to four hours, and that they are often long and tedious. Unless some of the Group IV cases are taken to the theatre early they may not be operated on until as long as twelve hours after their injury. This must increase the danger of infection.

Clerical Staff.—In our hospital two clerks are on duty in the reception ward and take down full particulars of each case for the E.M.S. forms in a hospital casualty record book. Each case is numbered, and clothes and valuables labelled and recorded and placed in a safe. The E.M.S. forms are filled in later from the record book. In this way all information is quickly and permanently available. Further requirements in connexion with the reception ward are: (1) emergency lighting that is independent of the electric mains; (2) a good supply of hot-water bottles (in case of electricity failure); (3) the temperature of the ward must be kept over 70° F.; (4) provision of a portable *x*-ray apparatus; (5) avoidance of overcrowding—only those actively engaged should be allowed in the ward; (6) plenty of hot drinks should be available.

Staffing.—A casualty clearing station must be prepared to treat a large number of casualties at all hours of the day or night with no warning. At the same time, in view of the long periods of inactivity, too many members of the staff must not be interned in the hospital and condemned to idleness and boredom. The classification above shows that there are a very few cases which need urgent operation, a larger number which need resuscitation before operation, and many which need operation sooner or later. Two surgeons on the premises are quite sufficient—one to operate at once if necessary, the other to undertake the difficult task of sorting. Two more surgeons should be on call, one of whom should be within twenty minutes' journey in a car—i.e., he could be fetched in forty minutes in the event of a telephone breakdown. Since nearly half of all operations have been orthopaedic it would be desirable that two of the four surgeons should have had orthopaedic experience. It is essential that one orthopaedic surgeon should be attached to the hospital.

Four operating tables worked simultaneously have been necessary to deal quickly with the larger groups of casualties received. A house-surgeon is required for each, and preferably an anaesthetist for each, although an experienced anaesthetist can supervise two cases simultaneously with a student or nurse to hold the head. One physician must always be on duty. There have been many cases on which a physician's opinion has been indispensable. One of his principal duties is assessing the response to treatment in a shocked case.

Operating Theatres.—Four operating tables are necessary—two in each of two theatres, so that an anaesthetist can supervise two cases. It has not been found necessary to keep trolleys constantly laid out. As soon as casualties are expected instruments are put in the sterilizers and are ready in good time for the early cases. Steam is used for sterilizing, since it is independent of outside power or gas, and can only be put out of action by a direct hit.

Wards.—It has been found to be useful to distribute the casualties after treatment among several wards rather than fill one ward. This lessens the strain on the nursing staff and appears to have no disadvantages. Extra nurses are drafted to the wards according to the numbers admitted. Some additional equipment is required, notably electric cradles and dressing instruments.

The above is a brief report of air-raid casualty work as experienced in our hospital. Various points arising from our experience are mentioned in the hope that they may be of use to others. The experiences of other hospitals would give us much useful information which would improve our organization, and I hope other medical officers will write up their work.

My thanks are due to Mr. C. H. Gray for advice and encouragement, and to Mr. G. Quist for assistance in the classification of casualties.

Nova et Vetera

CENTENARY OF THE PHARMACEUTICAL SOCIETY

The history of the Pharmaceutical Society of Great Britain provides a good example of the value of the union of men whose work in life lies along the same lines and whose duties to the State can be best done when they admit allegiance to a central authority of their own free choice and serve a common cause. A hundred years ago there were many practitioners of pharmacy well equipped by training and knowledge of drugs to make galenical preparations and dispense prescriptions; for it is absurd to suppose that between the highest grade of druggists as represented by William Allen, F.R.S., and the lowest grade as represented by those who added to their occupation the sale of "mops, brooms, bacon, butter, and a thousand articles beside," there was not a large intermediate class of capable dispensers, including a goodly number of apothecaries who preferred shop life to professional life, and the assistants who had been trained by them. Be that as it may, there was no sort of unity among the drug dealers of those days and no means, and little inclination, for the exchange of views and the sharing of experiences, by way of social contact. One interest they all had in common, and that was poaching on the preserves of the physicians, for counter-prescribing was a practice which the Apothecaries Act, 1815, had failed to suppress. It was from this common interest that the bond was woven which eventually united the druggists into a society of their own. It is an old story and need only be told in the briefest outline.

The Father of the Society

In the early part of 1841 a Mr. Hawes introduced in the House of Commons a Bill which sought to make it an offence for any person who was not a qualified doctor to recommend any medicine for the sake of gain. So strongly was this proposal resented by druggists, high and low, that they joined forces to oppose it. The opposition was successful, and on the flood tide of success a few leaders of pharmacy launched a scheme for establishing a permanent organization. A meeting was convened at the Crown and Anchor Tavern in the Strand, and on April 15, 1841, close on the heels of the withdrawal of the Hawes Bill, it was resolved, on the motion of William Allen, seconded by John Bell, "That for the purpose of protecting the permanent interests, and increasing the respectability of chemists and druggists, an Association be

now formed under the title 'Pharmaceutical Society of Great Britain'." Having regard to the high scientific attainments of William Allen, the first president, it is not surprising that plans for establishing a system of education for druggists were started immediately. Allen was a Fellow of the Royal Society who carried on business as a chemist and druggist in Plough Court, Lombard Street; in 1796 he had formed, with several other young men, the Askesian Society for practical scientific research, and three years later he had helped to found the British Mineralogical Society; in 1804 he delivered a course of lectures on natural philosophy at the Royal Institution, and he was for a time lecturer on chemistry and natural philosophy at Guy's Hospital. With such a man as its president there is little wonder that the infant society became imbued with his belief in the value of scientific education and turned to it as a means of raising the practice of pharmacy from the low level at which it stood in those days, so far as the rank and file of the calling were concerned. The wisdom of the Society's first council was soon to be seen, for by the time the organization was two years old Queen Victoria granted it a Royal Charter of Incorporation in which it was declared that the purpose of the Society was the advancement of chemistry and pharmacy and the promotion of a uniform system of education.

Medical Collaboration

As has been seen, the direct cause of the establishment of the Pharmaceutical Society at that particular date was the enmity which the ambitions of the physicians had aroused among the druggists. If the hatchet was now buried it was no doubt because the physicians saw clear evidence that the united druggists were making earnest efforts to improve the country's pharmaceutical service and so produce a class of men on whom reliance could be placed for sound drugs and accurate compounding. Already the effect of this was seen in 1849, for in that year we find the Provincial Medical and Surgical Association, the forerunner of the British Medical Association, in collaboration with the council of the Pharmaceutical Society concerning the parliamentary measure which was to become the Arsenic Act. The first Pharmacy Act (1852) was, in fact, largely the outcome of their collaboration, for one of the proposals made by a joint committee of the two bodies was that the sale of arsenic by retail should be reserved to medical men and chemists and druggists. This proposal could not be adopted by the Legislature because there was at that time no legal definition of the term "chemist and druggist," a fact which was made so clear to members of Parliament during the passage of the Arsenic Act that steps were soon taken to prepare one. Since then the British Medical Association and the Pharmaceutical Society have been in contact at many points: in more recent times there were, for instance, discussions arising out of National Insurance legislation in 1911, the Dangerous Drugs Act in 1920, the Select Committee on Medicine Stamp Duty, 1914, the Poisons Board, 1934, the Medicines and Surgical Appliances Advertisement Bill, 1935–6, and in 1938 the discussions regarding the differentiation between valuable and other medicines advertised only to the medical profession.

The centenary of a society is no small matter. To weather the storms of a hundred years needs not only stamina but good intentions well carried out. The Pharmaceutical Society began with the intention of raising the standard of pharmacy by educating those who practised it; a hundred years on we find the descendants of William Allen and his colleagues still carrying on the good work and the School of Pharmacy an integral part of the University of London. By encouraging and subsidizing research in the fields of pharmacy and sciences allied to it the Pharmaceutical Society has made great gifts to medicine.

For the past sixteen years Dr. Mazyek P. Ravenel has edited the *American Journal of Public Health*, which during his direction has achieved an unrivalled position in public health literature. The January issue commemorates the appointment of Dr. Ravenel as editor emeritus, and contains appreciations of his work from different men distinguished in public health services and a bibliography of his writings from 1891 to the present date.

DOCTORS HARD HIT BY THE WAR

HELP FROM MEDICAL RELIEF FUND

He was decorated for gallantry in the last war; and when an incendiary bomb set fire to his house some months ago, destroying his furniture, clothes, books, instruments, spare cash, and other possessions, Dr. A could "take it," though the financial consequences were very serious. He is a general practitioner who has been carrying on under difficulties in a much-raided district from which many of his patients have departed. He bought the practice only a few years ago. His bank, which provided the necessary capital, holds his investments as security for the loan. He has found that rent, rates, taxes, bank interest, insurance premiums, and other expenses, professional and domestic, absorb almost the whole of his diminished wartime income. But Dr. A has been carrying on, paying his way.

When the bomb fell Dr. A was determined to continue carrying on. But how to continue paying his way? There were vague reports in the Press about a proposed Government Bill to provide compensation for air-raid damage. At some remote date Dr. A might perhaps be able to recover at least part of his loss. Meantime he had to pay for board and lodging for himself and his wife. And he urgently needed new clothes, new instruments, and a second-hand car.

Fortunately for Dr. A, the Medical War Relief Fund had recently been established. He seemed just the sort of man, involved in wartime misfortune through no fault of his own, that the Fund was designed to help. He was granted a substantial gift of money to provide for immediate needs, and in addition a loan which he is expected to repay, without interest, when he is in a position to do so. The Fund has received from him the following letter: "I am overwhelmed with gratitude and cannot express to your Committee the heartfelt thanks I wish to offer them. My case is probably typical of many others, but I have never been dealt with so kindly in all my life. I will now be able to buy some clothes, and I shall use the money to the very best advantage. I am enclosing a separate letter accepting your loan, free of interest, and I undertake to pay it back when I receive my next panel cheque. I may at some time probably be able to let you have the whole of this amount back, when more peaceful times arrive. For the moment I cannot say more than 'Thank you.' Your gift has cheered me up tremendously."

Dr. B is a comparatively young man who practises as a specialist. It was a high-explosive bomb that came his way, seriously damaging his house and wrecking his garage. His private practice has largely vanished. His children are at boarding schools and his educational expenses are heavy. He has a few National Savings Certificates, but most of his savings have been invested in life insurance policies. In acknowledging a loan from the Medical War Relief Fund Dr. B wrote: "I feel that my colleagues have come to my rescue in a noble manner, and the keen edge of anxiety is removed. I shall of course repay the loan when I am in a position to do so."

Dr. C is a man of advanced age with a small practice and correspondingly modest expenses. His income has been reduced owing to loss of patients through evacuation, while his expenses have temporarily increased as a result of his house having been seriously damaged by enemy action. This exceptional expenditure presented a difficult problem to a man of slender means who was just making ends meet. The Medical War Relief Fund has solved the problem with a gift which will tide Dr. C over the emergency.

Dr. D is a general practitioner in middle age. He has been handicapped by health troubles, but in the years immediately preceding the war his professional income increased steadily, and although his house was heavily mortgaged his financial affairs were not such as to cause alarm. He is a veteran of the last war, and in his circumstances many a man would have been content in September, 1939, to consolidate further his position in civilian practice, leaving the uniform of the R.A.M.C. to the younger generation. Not so Dr. D. He served in France, but after Dunkirk he was obliged to relinquish his commission on the ground of ill-health. Meantime the income from his practice had diminished, and there was an awkward interval between the date when his Army pay

ceased and the date when professional accounts would become payable. He was in need of a considerable sum of money for current expenses and for the payment of pressing debts. The Medical War Relief Fund gave him the necessary amount, partly as a loan and partly as a gift, as it was thought that an obligation to repay the full sum would prove an unduly burdensome addition to his other commitments. Dr. D has written: "I wish to express my sincerest appreciation and thanks for your very generous gift and loan to enable me to re-establish myself in my practice after my discharge from the Army. I shall be refunding the loan at the very earliest opportunity to enable you to help others who may find themselves in my late predicament."

Dr. E, an elderly general practitioner, has given his life on the Home Front. The bomb which killed him destroyed his home and all his possessions. His reduced practice, situated in a relatively vulnerable area, is unsaleable. The Medical War Relief Fund could not undertake to contribute towards the maintenance of his widow for the remainder of her life, but it gave her a substantial sum to meet immediate necessities, and also assisted her to obtain a very satisfactory pension from another organization. She has left the committee of the Fund in no doubt as to her gratitude.

Dr. F was killed by a bomb when on duty at a first-aid post. Other bombs damaged his residence and his surgery. The widow will receive a pension of £1 17s. 3d. a week from the Government, and there will be little addition to this even if it is possible to sell the practice when the surgery has been repaired. Mrs. F has no relatives who can assist her financially, and she cannot at present undertake remunerative work as there are children to be cared for. The Medical War Relief Fund has granted her a gift which will be paid in annual instalments over a period of five years. The money has been handed to the Royal Medical Benevolent Fund for administration, and this body will therefore be able to maintain contact with the family and advise Mrs. F if at a later date additional help is required for the completion of the children's education.

Aims and Constitution of the Fund

It might happen to any one of us, though we are not all exposed to equal risks. It would be good to know that there would be help for our wives and children if they should be numbered among the unfortunate; to know that our colleagues had created a fund to which they could appeal without humiliation, a fund which we ourselves had helped to establish, a fund that could come to the rescue in a manner worthy of a generous profession. It is to achieve this object that the Medical War Relief Fund has been instituted, and the above cases illustrate the work that is being done.

The purpose of the Fund is defined as the temporary assistance of registered medical practitioners and their dependants who find themselves in financial straits as a direct result of war conditions. Applicants must be "registered members of the medical profession, British subjects domiciled in England, Scotland, Wales, the Isle of Man, the Channel Islands, and Northern Ireland, and such of their dependants as the Committee may determine." Assistance takes the form of a gift or a loan free of interest, or may be given partly as a gift and partly as a loan. The Fund is administered by a Committee representative of the British Medical Association, the Royal Colleges, and the Royal Medical Benevolent Fund. The cost of administration is very small and it has not been necessary to acquire special office accommodation or to appoint a special staff. The Honorary Treasurer and Honorary Secretary of the Fund are officials of the British Medical Association and the cost of their work, which includes much correspondence connected with the collection of subscriptions, is defrayed by the Association. A Distribution Subcommittee has been appointed to consider applications and vote awards. The Royal Medical Benevolent Fund was invited to nominate a number of the members of the Subcommittee, and the Secretary of that body acts as Secretary of the Subcommittee.

More Support Needed

The subscription lists already published show that many individual practitioners, B.M.A. Branches and Divisions, Local Medical War Committees, Local Medical and Panel Committees, and other professional organizations have responded to the appeal in a magnificent way. At the end of March, 1941, the contributions exceeded £20,000, and more than £4,000 had already been expended since the date of the first awards—that is, during a period of four and a half months. Further subscriptions will certainly be needed, for the number of applicants is increasing and will doubtless continue to increase as the war goes on. Every member of the profession is asked to send a contribution, however modest. Collections are being made in many areas, but any practitioner who has not received a local appeal may send his subscription to the Honorary Treasurer of the Medical War Relief Fund at B.M.A. House, Tavistock Square, W.C.1. Cheques should be made payable to the Medical War Relief Fund. The latest list of contributions is published in the *Supplement* this week.

Doctors will not fail to discharge their responsibilities, whatever the risk, and it seems inevitable that many of them will suffer. Is it not both a duty and a privilege to ensure that in their hour of need they will be able to echo the words of one who has been helped by the Fund and say that they too are "proud of their profession"?

AFTER-CARE OF MENTAL PATIENTS

The annual meeting of the Mental After-Care Association was held on March 26, with Colonel Henry Yellowlees in the chair. H.R.H. Princess Arthur of Connaught was elected president in place of the late Lord Wakefield. Incidentally, it was announced that Lord Wakefield had left the association a bequest of £5,000, which had placed it in a more satisfactory position than it had ever enjoyed. Colonel Yellowlees presented the annual report, which was a record of many-sided services continuing in full vigour notwithstanding the distractions of the war. The total number of patients who had been dealt with during the year was 2,663. Over 600 first visits were paid to the homes of patients. The convalescent homes, all of which have been brought from the coast inland, had accommodated 303 after-care and 237 early-care patients (meaning, by the latter, patients ill but not ill enough to be certified). The number of patients boarded out was 372. One of the most recent additions to the association's activities has been in finding accommodation for suitable hospital patients, thus setting beds free for more urgent cases. At present the association is arranging to take another large number from various L.C.C. hospitals. Still more recent is some work done at the request of the Ministry of Health in air-raid shelters and rest centres.

An address was given by Miss E. D. Vickers, the late secretary, who has held the post with conspicuous success for the last twenty-five years. She described how in cottage homes patients were assisted over the difficult transition from hospital to everyday life. At the end of the last war there was an enormous influx of early-care patients, and the same thing would probably happen again. Another type of home was established for patients who could be discharged but would never be able to take care of themselves. These were also a great success and enabled old people to spend their last days as members of a family instead of in an institution. As for the holiday homes, she thought it a wonderful tribute to the patients and those in charge of them that in a year when 1,200 patients were sent for a fortnight's holiday only one complaint was received from a member of the public.

T. B. Patel and B. P. B. Naidu (*Ind. med. Gaz.*, 1940, **75**, 730) state that among cases of small-pox admitted to the City Hospital at Bombay nearly 50% were unvaccinated. A very large percentage of admissions were from the adult population, as the immunity conferred by vaccination does not wear off until the tenth year. The mortality among the vaccinated was low (3.3 to 3.7% up to 20 years of age), as compared with that among the unvaccinated, which was 17 to 60%. Administration of sulphanilamide reduced the mortality in confluent cases by about 30%, but had no influence on the course of the disease except in the septic type, and no effect on haemorrhagic cases.

Reports of Societies

FACTORS INFLUENCING THE HEALING OF WOUNDS

At a meeting of the Medical Society of London, on March 31, Dr. G. W. GOODHART presiding, a discussion took place on factors influencing the healing of wounds.

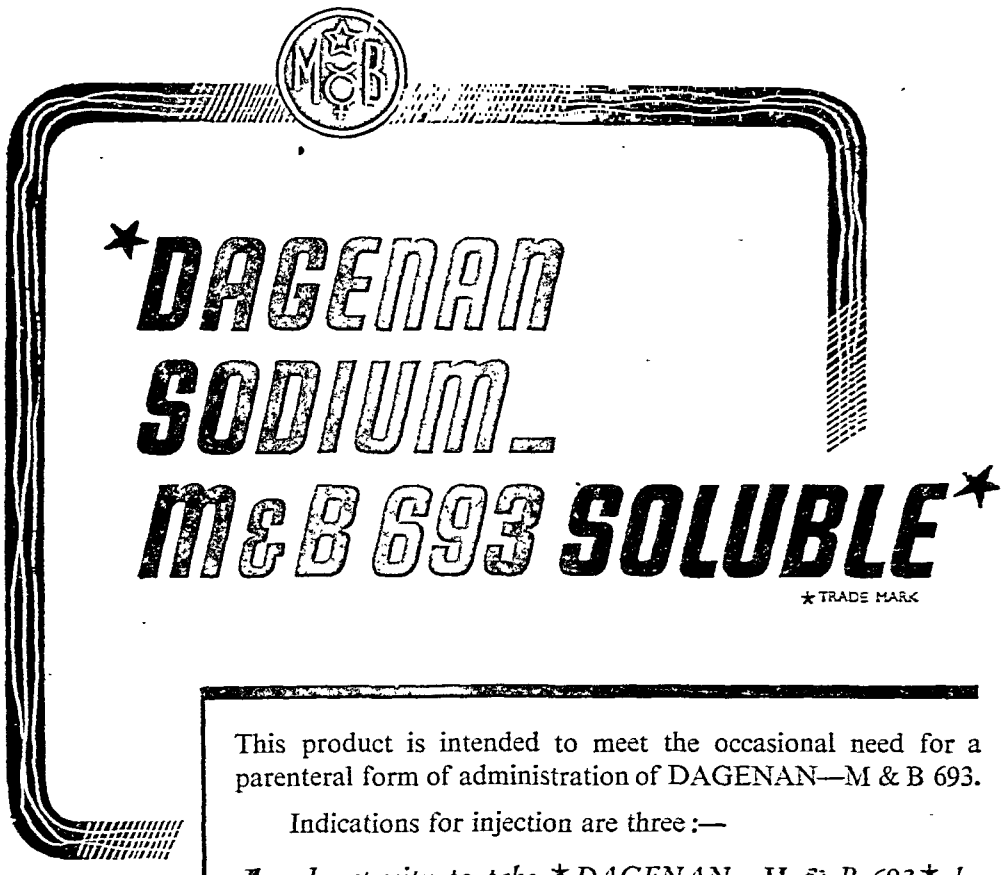
Dr. J. M. CONVERSE (U.S.A.) opened by referring to the stimulus which war gave to surgery, and recalled the work of Ambroise Paré, of Larrey in the Napoleonic wars, of Carrel, Almroth Wright, and others in the last world war, and of Trueta in the Spanish war. The subject of wound healing was too vast to cover in a single address, and he could only select certain factors. He drew attention particularly to nutritional ones—the value of the protein factor, especially in severe burns, and of vitamin C—also to the manner in which healing was interfered with by infection, which produced tissue destruction and devitalization and delayed the repair of wounds. Another factor of great clinical importance was contraction, and yet another the closed-plaster treatment of wounds. On this last subject he said that at the American Hospital in England certain impressions had been gained—based, however, on too small a number of cases, generally compound injuries. Closed plaster did seem to control local infection. It also seemed to promote repair of connective tissue in a remarkable manner. Furthermore, granulations observed in the wounds even after a month still presented the characteristics of young granulation tissue. But although closed plaster might favour connective tissue growth it did not seem to favour epithelial tissue regeneration. The epithelium that grew around these wounds under plaster grew extremely slowly and was of very poor quality. After the bone repair had been assured by immobilization in plaster it seemed a hardship to keep the patient in plaster for months because his superficial wound had not healed. It was possible that the inhibitory effect of the closed plaster was due to the presence of the plaster itself, and he believed that was Dr. Trueta's opinion. If the bone lesions admitted, the patient could be taken out of the plaster and the wound treated in the usual manner with the aid of chemotherapy. When the plaster was changed, if the appearance of the wound showed that it was ready to receive an epithelial covering skin-grafting might be done, again in combination with the use of sulphanilamide. This had been carried out in three cases in his experience and had proved successful. It was possible that observation of the bacterial condition in the course of the change of plaster would be helpful, and if the patient in whom the haemolytic streptococcus was present had sulphathiazole put into the wound it was very likely that at the next change of plaster no sign of the streptococcus would be found.

On the general question of chemotherapy as a means of countering the infection which hindered wound healing, Dr. Converse gave the example of a wound around which there was a marked inflammatory reaction with oedema. This oedema around the wound prevented the contraction which was due to the pull of the fibroblasts, and by interfering with contraction had a remarkable effect in preventing the wound from healing. In one such case sulphanilamide powder was used as a local treatment, and within two days the wound had shrunk to half its size and the test for streptococci was negative. Whether it was due simply to the subsidence of the oedema or to the contraction which was thus enabled to take place, the fact remained that this was an example of the influence of infection in preventing a wound from healing and of the value of chemotherapy.

Dr. Converse concluded by expressing the view that the present trend of treatment of wounds suggested that this war would see the more general application and use of skin grafts, not by specialist plastic surgeons, but by surgeons in general.

The Anti-scorbutic Factor

Mr. ALAN H. HUNT said that wounds failed to heal when there was an absolute deficiency of vitamin C, though it might be that a relatively low concentration of the vitamin was all that was necessary in man. He proceeded to describe an experiment on guinea-pigs—animals far more susceptible to scurvy than man—to illustrate the sub-scurvy stage, the effect of partial deficiency of the vitamin on the formation of collagen fibres. Some observations on human patients showed that the critical level of vitamin C in the formation of collagen in man was probably well below saturation point, but there was sufficient evidence to justify giving full doses of vitamin C to certain groups of patients, preferably before operation, or as soon as possible after. Cod-liver oil applied locally had a beneficial effect.



He also mentioned *x*-ray therapy in the treatment of wounds. Cellular proliferation and therefore the quantitative production of callus were inhibited in proportion to dosage, but the cells themselves were supposed to mature more rapidly and therefore to produce a more fully developed interstitial matrix. The effect of *x* rays, therefore, was beneficial so long as minute doses were used.

Mr. R. T. PAYNE spoke of the importance of the nutritional state of the patient, and in illustration gave an account of the post-mortem findings in fifty-one cases in which death had followed partial gastrectomy. Of this number, sixteen had had general peritonitis, and in twelve of these at the site of the operation on the stomach there was complete evidence of non-healing. Another third of the cases died of pulmonary infections, which might be held to represent another failure of repair—a failure to overcome potential infection. In these malignant gastrectomy cases the anaemia was often extremely grave, and was not always corrected before operation. Another point suggestive of the importance of the nutritional state was the loss of weight. It had been shown that in operations on the gastro-intestinal tract the prognosis was directly related to the antecedent loss of weight. In some figures quoted, among patients who had lost more than 20% of their original body weight the mortality was only 3.9%, while in patients who had lost more than 20% the mortality was in the region of 33%. By paying more attention to the nutritional state, not only mortality after operation but also morbidity would be reduced. So often the post-operative diet was considered only as a question of calories, which was but a part of the dietetic factor.

General Discussion

Mr. ZACHARY COPE, as one who had seen a good deal of scurvy abroad and something of it in this country, said that two or three days after taking a normal amount of the anti-scorbutic factor the patient was well, so that it seemed strange that a patient in the condition of sub-scurvy to which Mr. Hunt had drawn attention should require such relatively large doses of the substance as were indicated by his experiments. Was there some other factor? Mr. E. W. RICHES had been interested to hear Dr. Converse say that the general surgeon should be prepared to cover a wound with skin and not leave it to the specialist plastic surgeon. That was what the plastic surgeons in this country were now saying. Dr. G. W. GOODHART thought it highly probable that the ascorbic level varied enormously in different people, although healthy people required a very large amount by mouth before they would excrete it in the urine. Sir THOMAS DUNHILL said that there was a fairly good ascorbic margin, but if by tests carried out in this way surgeons could be made a little more sure of the condition of the case before they operated, lives would be saved. The progress of surgery lay along the path of ever-increasing pre-operative as well as post-operative care. Not the finest post-mortem work in the world would make up for poor surgery.

Dr. CONVERSE, replying on the question of scurvy, referred to an experiment by Crandon carried out on himself. Crandon went on a vitamin-C-free diet from October of one year to May of the next. He became free of vitamin C in the plasma at the end of forty-two days, but the ascorbic acid persisted in the leucocytes for 122 days. He developed clinical scurvy in five months. An experimental wound done on him at the end of three months healed perfectly normally; this was when he had zero ascorbic acid in his plasma, but before it had disappeared from the leucocytes. At the end of six months an experimental wound failed to heal and showed

This product is intended to meet the occasional need for a parenteral form of administration of DAGENAN—M & B 693.

Indications for injection are three:—

1 *Incapacity to take ★DAGENAN—M & B 693★ by mouth.*

2 *Failure to obtain an adequate blood concentration with oral administration.*

3 *Necessity for obtaining maximum effect as rapidly as possible.*

DAGENAN SODIUM—M & B 693 SOLUBLE will replace DAGENAN—M & B 693 in oil suspension which was introduced to meet the necessity of a product for injection before DAGENAN SODIUM was evolved.

Supplies { DAGENAN SODIUM—M & B 693 SOLUBLE
Boxes of 6 x 3 c.c. (1 gramme) ampoules at 8s. 0d.
Subject to our usual discount.

the characteristic lesions which the sections shown by Mr. Hunt had depicted.

Mr. HUNT, also in reply, said that it was the custom at his hospital to give vitamin C in all cases in which a major abdominal operation had been performed, particularly where a viscus had been opened; in all cases which were seriously wounded; in all cases where there was evidence of nutritional deficiency; and, recently, in all cases in which rapid healing of the wound was desirable—that is, where it was specially desired to have clean, almost invisible scars—and he was sure that the scars in the patients who were saturated were on the whole much better than those in the patients who were not. In seriously deficient cases they played for safety and gave 1,000 mg. of the ascorbic acid preparation per day for three days, afterwards maintaining the saturation by giving 100 mg. per day for about three weeks while the wound was healing. In ordinary cases these doses were too large, but in certain cases with achlorhydria present they were too small. When the substance could not be administered by the mouth it was given intravenously. Recently they had tried intramuscular administration, and it seemed satisfactory, allowing for the fact that intramuscular administrations were rather uncomfortable for the patient.

Sir JAMES WALTON proposed a vote of thanks to the openers, particularly to the visitor from the United States, and mentioned the debt which British surgeons owed to their American confreres. The vote of thanks was seconded by Mr. W. E. TANNER and heartily carried.

*** Some of the problems in the healing of wounds are discussed in a leading article at p. 560.

Correspondence

Medical Planning Commission

SIR,—In the generous space which you allow to correspondence on the Medical Planning Commission you have recognized the importance of the issues involved and the value of wide interest in the project. I feel, however, as Chairman of Council that the time has come for a reply to some of the criticisms which have been made and for an emphatic correction of erroneous views which apparently prevail as to the nature and objects of the Commission. At any other time the whole matter would have been discussed at a meeting of the Representative Body, but circumstances rendered this out of the question. At the same time the matter is urgent and can by no means be left until the end of the war, for if we medical men and women do not make up our own minds we may find ourselves faced by a solution of the medical problems of the country in which we have not been consulted and which we are forced to accept. One would have thought that even thirty years is scarcely a sufficient period to produce complete amnesia.

As has in fact been very fully stated, the object of the Commission is to discuss the possibilities which the future after the war holds for our profession and to present these possibilities in the form of a reasoned report. Obviously it has no executive power, nor can it bind either the British Medical Association or any of the bodies which are represented upon it. But it *can* examine the whole field, it can take evidence and gather full information, it can and I hope that it may reach definite conclusions, and it can then submit its findings to every branch of the profession for acceptance or rejection. For such a purpose I maintain that the Commission has been properly constituted in accordance with the very explicit requirements of our constitution, that it would be impossible to devise a body better suited to its purpose, and that it deserves the fullest support and confidence from the whole of our profession.

It would seem from the correspondence that very few medical men have the vaguest idea of the complexity of the problems by which the Commission will be faced, and the pathetic suggestion has actually been made that they should be referred to the profession in the form of a questionary. Those of us who have studied the subject realize that if at the end of a year's hard work a tentative conclusion has been reached on even a few of the problems the Commission will deserve congratulation. If it can then present a reasoned plan for the consideration of the profession as a whole, it will have earned our gratitude. I feel that I am paying it a very high tribute when I express my firm belief that it is equal to its task.

The appointment of the Commission was carried out with the full democratic machinery of the Association so far as it is available in wartime. The Council of the Association after a full discussion decided that in the interest both of the public and of the profession a Commission ought to be established to study the effects of the war on medical practice and to consider the direction in which medical practice should develop in the reconstruction of national life after the war. It decided further that, although the Association would give the Commission the fullest support and place all its resources at its disposal, it should be an entirely independent body representing the whole medical profession and so constituted as to speak for the whole profession with unquestioned authority. With this object negotiations were opened with the three Royal Colleges, and after some months of discussion they all agreed to co-operate in the most cordial manner. The three Scottish Corporations, the Society of Medical Officers of Health, the [illegible] the Medical Women's Federation, and [illegible] dical Committee were all invited to [illegible] all have accepted the invitation. It is difficult to see how a manageable body could have been formed on a wider basis or one which could represent the profession with greater authority.

Apart from the representatives of important medical bodies a number of individuals were invited to serve on the Commission on account of the interest which they had shown in the development of medical practice and the constructive work which they had already done, and after most careful selection they were approved by the Council as representing every branch of practice. Where any branch appears to have been overlooked, or where the services of any individual seem of special value, it will still be open to the Commission to add to its number if it so desires.

In the composition of the Commission the greatest care has been exercised to maintain a just balance of the many interests involved, and I venture to think that this has been obtained. If the representation of the great medical bodies has meant the inclusion of a large number of specialists, there are still more than twenty members chosen for their experience of general practice, and from what I know personally of their expert knowledge of their subject and their skill in debate and negotiation they are likely to exercise an influence upon the findings of the Commission out of all proportion to their number. Moreover, it is probable that most of the work will be carried out in committees devoted to special branches of practice, and in each of these the special branch involved will of course have a preponderant representation.

The age of the members of the Commission has aroused much criticism, with which I have the greatest sympathy but which it is very difficult to satisfy. In the first place, there are very few young men with either the experience or the interest required, and in the second all those who would in normal times be available are engaged with His Majesty's Forces. In spite of this it will be found that eleven members are under 45 and thirteen others are between 45 and 55, and surely all these would be accounted young in any branch of political life. But I feel certain that every member of the Commission will realize that he is planning not for himself or his contemporaries but for those who will follow him in the new world after the war, for the students whom he has taught, for his partner who is in the fighting line, perhaps for his own son.

Moreover, use will be made of the machinery of the Association to test the Commission's work as it proceeds, and the views of the Divisions and Branches will be invited before coming to any important conclusion, while the representatives of the different bodies involved will certainly wish to consult the bodies which they represent. In this way the Commission would carry with it the profession as a whole and would ensure that its ultimate findings met with general support.

Finally, it has been suggested that the work we are undertaking is properly the function of a Royal Commission, and that we are arrogating to ourselves a position to which we have no right. With such a view I most emphatically disagree. It is perfectly true that the reorganization of the medical services of the country may in the end have to be undertaken by a Royal Commission, and that many interests are involved besides those of the medical profession. But how can any Royal Commission commence its work without our advice, and how can it provide a medical service for the nation without the support of those who alone are in a position to understand its needs? Unless we have ourselves made up our minds as to what is required legislation will only result in chaos.

We have to face the fact that after the war changes in the medical services of the country, perhaps of a revolutionary character, are inevitable. It is of the utmost importance that the medical profession should make up its mind what these changes should be, not in its own interest alone but in the interest of the whole community, and this can only be done after a close study of the very intricate problems by a body specifically chosen for the purpose and commanding the confidence not only of medical men but of the whole nation. I venture to think that the Commission which has been formed satisfies this very exacting criterion, and that when its report is finally submitted to the consideration of a Royal Commission it will form the foundation of a new era in the medical services of the country.—I am, etc.,

London, W., April 4. H. S. SOUTTAR.

Crush Injuries

SIR,—I would like to add my meed of praise on the magnificent series of articles on this subject in your issue of March 22. They furnish a number of facts of the utmost importance. There are three points on which I should like to make some comment:

Traumatic Arterial Spasm.—Some anxiety about the blood supply of the limb was felt in the majority of cases, but in only two of the Bywaters-Beall series was the artery explored. I should like to draw attention to this phenomenon of arterial spasm, or arterial "stupor," as being a quite common clinical entity. With injury, a direct blow, or blood extravasation in the neighbourhood, the artery goes into spasm. John Hunter wrote of it, and Griffiths[1] in a recent Hunterian Lecture stressed its importance, especially in Volkmann's contracture. That it is not the tension of the oedema which obliterates the vessel is well illustrated by Bywaters and Beall's first case. Here, according to the report, though the leg was cold and was amputated for it, there was no arterial damage, no oedema deep to the fascia, and only blood extravasation around the popliteal artery. I would urge, from my own experience and a growing literature; that if the cause is local and the radial or tibial pulse has not returned at the end of six to twelve hours, full exploration is advisable. If delayed for more than twenty-four hours it seems that, as in embolism, thrombosis vitiates the result. Exposure of the vessel, clearing it and not necessarily doing a periarterial sympathectomy, relieves the spasm immediately or within a few hours. The incision left unsutured adds nothing to the risk of infection of the damaged area. Continued spasm is one factor in providing "the particular opportunity," as Mr. Ogilvie described it, for gas-gangrene infection.

Sulphapyridine Haematuria.—Bywaters and Beall discuss the possible role of sulphapyridine in this condition. As observed by Long,[2] 8% of cases undergoing sulphapyridine therapy develop haematuria, and its importance therefore cannot be ignored. It is the custom of many medical officers to include sulphapyridine in their intravenous "cocktail." I know of two such cases that developed oliguria and blood in the urine—one being fatal after a dose of only 4.5 grammes. Taking all the sulphonamides, renal complications are apparently four times more likely with sulphapyridine, and this forms a strong reason why, especially in burns, shock, and now crush injuries, its systemic effect should be avoided.

Untreated Shock.—As Mr. Franklin and Mr. Douglas' point out, renal failure is not encountered in the usual "unburied" crush injury. There is one difference: the trapped patient receives no treatment. The oppressive anxiety, the cold, the fixation of the chest and muscles, all tend to increase the shock. The M.R.C. point out that after shock has existed for some time an irreversible process sets in leading to permanent damage. They stipulate no time, for obviously there are many factors that influence it. But we know from the work of Bayliss[4] that in cats in which shock was induced and untreated there was after two hours no recovery with any form of treatment. Best *et al.*[5] in their work on the use of plasma for haemorrhage showed how essential rapid administration is for recovery. And the kidney, with its refined function, is particularly sensitive to changes in the blood supply. In experiments on animals even transitory interference with either their arterial or their venous supply produces albuminuria. Clamping of the renal artery for from ten to thirty seconds will cause the secretion to stop, followed by the appearance of albumin in the urine. As Bywaters and Beall point out, secretion also ceases if the blood pressure falls below 75 mm. Hg. And it must be remembered, in assessing the data, that the first specimen of urine passed may have been in the bladder before the "incident." The fall in blood pressure associated with shock affects the circulation of the brain and the heart muscle, as well as the kidney. Coronary thrombosis or heart-block may follow, often only twenty-four hours later, if there has been a prolonged fall of blood pressure just as in spinal anaesthesia. It may explain the cardiac changes and the sudden death in some of these cases.

I note these facts to urge that shock be not treated expectantly, as is being advocated in some of the recent articles on air-raid injuries. Nor must it be a leisurely affair, with slow drip over hours, if the irreversible factors are not to come into play. It seems pertinent to suggest, therefore, that besides the oxygen which Sir Leonard Hill[3] recommends, fluids to convey it are advisable.

Lastly, may I congratulate the authors on the clarity with which the problem was presented. It affords a striking illustration of co-operating with the physicians in the treatment of casualties, and the advisability of their more frequent attendance in the operating theatre and surgical wards.—I am, etc.,

March 31. SOL. M. COHEN, Surgeon, E.M.S.

SIR,—I have read with great interest the cases of crush injury with associated renal failure described in your issue of March 22, and I think that the various teams are to be complimented on the thorough nature of the investigations made and treatment given under what must have been trying conditions.

In view of this thoroughness it is with some diffidence that I suggest an intravenous solution which has, apparently, not yet been used. It is isotonic sodium sulphate solution given by the constant intravenous drip up to a maximum of three litres a day. The use of this solution is based on work published in the early years of this century by Crile on the permeability of the renal epithelium to various salts in isotonic solution; and first applied clinically in Edinburgh and published by Band in or around 1934 in the *Edinburgh Medical Journal*. I have had some personal experience of its use in the oliguria and anuria met with in obstructive lesions of the genito-urinary tract associated with poor renal function. In them the diuresis is considerable, even after an anuria lasting for many hours.

The two types of cases are not strictly comparable, but in the cases of obstruction the lesion is certainly an active congestion of the kidney, and it is therefore possible that the isotonic sodium sulphate solution might, in conjunction with plasma, restart normal renal secretion in these crush injuries. In conclusion, I must apologize for the vagueness of the references, but at the moment I have no ready access to the literature.—I am, etc.,

March 26. A. IAN L. MAITLAND, Surgeon-Lieut.-Commander, R.N.V.R.

Treatment of Burns

SIR,—One has read with interest the article by Dr. J. M. Robson and Mr. A. B. Wallace (March 29, p. 469) on a further treatment of special burns, incorporating as it does the use of sulphonamides and the principle of osmosis, and adopting once more repeated dressings. May I, at this juncture in the development of burn treatment technique, suggest for investigation the value of the closed method in selected cases? It may be used well in children for burns of the upper limbs, and it possesses some advantages—for example, avoidance of painful dressings, rapid separation of sloughs, and saving of time. A viscopaste bandage is applied over the area, and in the second-degree burn is usually left on until healing is complete, though it may be renewed once during that time. Its value in deeper burns lies in rapid separation of the slough. The ultimate result is good and it is striking how soon the child forgets its injury. This method precludes the use of sulphonamide locally, except initially. With regard to the paste used by Robson and Wallace, while the osmotic action is of value in small areas where oedema is present, it would presumably be a disadvantage over larger surfaces. Would it be possible to incorporate sulphonamide in a more or less isotonic base for general application?—I am, etc.,

Turriff, Aberdeenshire, March 31. G. D. ROCHE.

SIR,—"A small percentage of disasters is enough to condemn any method"; at least, so reads the last sentence of the leading article on the treatment of burns (March 29, p. 484). On the same hypothesis almost every known surgical procedure would be precluded, for not many medical students qualify without having seen treatment result in disasters a good deal worse than a stiff hand. Of course failures occur in the application of any form of treatment. It is for us to weigh success against failure in rival forms of therapy. Burnt hands have been given the tannic acid treatment for many years with much success and undoubtedly a small percentage of failures (and no "disasters" in many surgeons' experience), and treatment with saline packs, recommended recently, after no comparable period of trial, may produce even worse failures. I have seen one.—I am, etc.,

Redhill, Surrey, April 1. NORMAN PITT.

Chemotherapy in Otitis Media

SIR,—Most ear, nose, and throat surgeons admit that large doses of sulphanilamide and sulphapyridine can abort otitis media during the invasive stage, and in the right case can favourably influence the course of the disease during the suppurative process, when haemolytic streptococci or certain types of pneumococci are the cause. Dr. J. B. Jessiman confirms this view in his careful article (March 15, p. 399). I venture, however, to suspect, from his excellent description of "bullae and sacs," that five of his seven cases were actually of otitis externa haemorrhagica, which responds well to chemotherapy, unless it is complicated by otitis media—difficult to discern beyond the blebs. There is not often a great loss of hearing in these cases, which occur mostly in an influenza epidemic. However, this is not the point. The real issue is whether we are to treat cases of otitis media by paracentesis or chemotherapy, or whether we are to watch their agony until the drum bursts.

I would say that many cases (perhaps the majority) of otitis media get better whatever the treatment, and may not even get to the stage of discharging. Such excellent results are often attributed to the latest form of treatment. The remaining cases are serious and may lead to fatal complications, which we must leave no stone unturned to prevent. Many of these are referred to specialists, who, from a very large series of cases, are beginning to assess the true value of these powerful drugs. It is in the serious cases that we must compare the results of any treatment.

In my experience the result of an early (but above all not too early) paracentesis is in most instances little short of miraculous, and I am sure that the mental trauma, whatever that may be, of a half-minute operation done in bed, probably at night, must be negligible compared to a week's earache coupled possibly with the nausea, vomiting, and cyanosis of chemotherapy. I hope the day will soon come when this simple operation will become part of the armamentarium of every general practitioner. It can be done easily with an electric auriscope and a suitable knife (long enough to pass through the instrument) under a very short anaesthetic, although the specialist may appear to need more. I have never seen any harm come of paracentesis, and I cannot remember a permanent perforation resulting where the case had the proper after-treatment.

Chemotherapy is of value before pus is formed, but cannot in my opinion help much once there is pus and the ear discharging, unless there is an associated high temperature or septicaemia, when it is extremely useful and has prevented much premature mastoid surgery. We must, however, be careful not to make our patients worse. For instance, the temperature and pulse may come down, and the leucocytosis too; yet there is still mastoid tenderness. What is happening? What is one to do next? Like other ear, nose, and throat surgeons, I have had to do some nasty mastoids which might have been avoided if the drum had been opened and the chemotherapy discontinued.

As for the waiting and watching with fomentations and anodynes, which is not without its supporters, I am prepared to confess that if paracentesis is delayed for several days the cases often do better than some others. This may be due to the fact that they may not be bad enough to cause rupture of the drum. I must, however, regard it as nothing short of barbarous to force days of unnecessary pain (which is intense) on a child or anyone else when it can be relieved so easily and when every day increases the danger of intracranial complications, to say nothing of mastoiditis and deafness. I believe that it will be a long time before we know all about these new and wonderful drugs. Their indiscriminate use for mere earache will lead to their disuse. Let us instead, like Dr. Jessiman, control their effect by careful observation, remembering all the time that cases do very often get better without any treatment whatever.—I am, etc.,

York, March 18. R. THOMAS.

Convulsion Therapy by Electricity

SIR,—It was with some surprise that I read Dr. Gerald Caplan's paper (March 29, p. 479) on the use of faradic current as an approach to the therapy of mental disease, for although acquainted with the work of Berkwitz I did not expect to find history repeat itself to such an extent in this country. During the nineteenth century methods closely similar to those adopted by Berkwitz and Dr. Caplan were described by Arndt, Erb, Allbutt, and others, and Blandford in 1896 expressed the opinion that the apparent improvement noted in some psychotics was due to the moral rather than to the physical effects of the treatment. This observation was no doubt occasioned by the distress that accompanied the treatment. Allbutt's description of the method employed by him is of interest, as it was carried out in this country and described in the West Riding Lunatic Asylum Medical Report for 1872. The current was obtained from modifications of the Daniell cell and was applied to the head for ten minutes. The immediate effect of this was to "tranquillize," an effect which Allbutt did not think was due to the mere "astonishment" evoked by the procedure, for it did not lessen on repetition.

In America reluctance to adopt at once the unmodified method of convulsion therapy by electricity is not at all surprising when one reflects that there judicial execution is mainly carried out by high electric potentials, and indeed inept comparison has been made in this country with the methods of Sing Sing (*Lancet*, 1939, 2, 1373). By the method adopted by Berkwitz and now described by Dr. Caplan considerable fear and pain are aroused during the application of the current, although Berkwitz does not think there is any real "mental anguish." It is to allay this as much as anything else that the intravenous anaesthetic is given. It is the elimination of fear that is one of the chief claims of electric convulsion therapy to consideration.

With reference to the remission obtained by Dr. Caplan, while the occurrence of the convulsion with low currents is of interest it was possibly brought about by summation of subliminal stimuli, or by an increase in the effective current

as the head resistance dropped, which it no doubt did with passage of the current. The convulsion, too, may have had a direct bearing on the remission, for it was only after this occurrence that it was decided that the patient was well enough for treatment to be discontinued. Finally, the imputation of respiratory and brain complications to convulsion therapy in general is misleading, for I am unaware of any such having been ascribed to electric convulsion therapy, although one account records vertebral fractures in two cases. At this hospital 130 patients have undergone electric convulsion treatment, with a total of some 1,800 major fits, without the occurrence of any complications, and I trust that Dr. Caplan's unwarranted statements regarding the dangers of convulsion therapy will not prejudice others against the electric convulsion method.—I am, etc.,

JAMES S. MCGREGOR.

Warlingham Park Hospital, March 31.

Cerebral Venous Thrombosis after Childbirth

SIR,—We have read with interest the article by Drs. J. Purdon Martin and H. L. Sheehan (March 8, p. 349). As we have seen two cases of this condition in the last month, it seems advisable to record them in support of Martin and Sheehan's statement that this complication of childbearing is less uncommon than might be supposed. The clinical features conform in general with those described in the original article, but neither patient experienced fits or coma. Moreover, the diagnosis cannot be proved because both patients recovered. The rapid disappearance of the paralysis of the first patient was remarkable, but the improvement in the second patient is much slower.

Case 1.—A 4-para aged 37 was admitted to hospital on February 13, 1941, three days after delivery of a stillborn child. The stillbirth was due to a prolapsed cord. There was no abnormality until the morning of the third day, when loss of power in right arm and leg was noticed. This spread rapidly, and within a few hours a complete right hemiplegia was present with loss of speech. The elbow-, knee-, and ankle-jerks on the right side were exaggerated and the right plantar reflex gave an extensor response. The blood pressure was 130/90. There was no albumin in the urine. The temperature was 99° F. on the third morning and 99.8° on the fourth. Blood examination showed a moderate anaemia: R.B.C. 2,600,000; haemoglobin 50%; W.B.C. 9,750; blood N.P.N. 37 mg. per 100 c.cm. Wassermann, negative. No abnormality was found in any other system. The hemiplegia improved fairly rapidly, and when the hospital had to be evacuated a month later she had almost completely recovered, but walking showed up the weakness of her leg.

Case 2.—A primigravida aged 21 was admitted to hospital on February 26, 1941. She had been attending the hospital's ante-natal clinic. There was a history of rheumatism in childhood. She had mitral stenosis, but this lesion was well compensated. A trace of albumin had been found in the urine on February 13. The admission was arranged because of the premature onset of labour at thirty-two weeks. On February 27, as the labour was progressing very slowly, the membranes were artificially ruptured, and this was followed by a normal delivery. The first four days of the puerperium were uneventful. On March 3 at 8.30 p.m. she complained of breathlessness, cough, headache, and pain in the right side of the chest. Blood pressure 130/90. At 10 p.m. she became very restless, breathing was distressed, and she complained of a sharp pain in the right thigh. The pulse rate rose to 140. She was given omnopon gr. 1/3. An hour later she developed a complete left hemiplegia. Temperature 99.4° F., pulse rate 120. Her breathing was now less distressed. The left biceps and supinator reflexes were exaggerated, as was the left knee-jerk. Ankle clonus was present and the left plantar reflex gave an extensor response. Wassermann, negative. She was stuporose at first. (The chest symptoms in this case suggest the possibility of pulmonary thrombosis as an added complication, as in Case 2 of the original article.) The paralysis remained complete until March 7, when she was able to raise her left leg. The plantar reflex still gave an extensor response. By March 11 she could flex the left knee, raise the left leg fairly well, and raise the arm slightly from the shoulder. All these movements were "flail-like." The face remained paralysed. There has been very little further improvement up to date. On March 18 she complained of pains in the chest and difficulty in breathing; she was restless and cyanosed about the lips. These symptoms settled down after two injections of omnopon gr. 1/3. There are now signs of probable thrombosis in the left leg.

We wish to thank our house-surgeon, Miss Jolly, for the careful notes kept on the progress of the second case.—We are, etc.,

ARTHUR A. GEMMELL.
T. N. A. JEFFCOATE.

Liverpool, March 29.

Night-blindness and Vitamin A

SIR,—I was interested in the annotation (March 22, p. 446) on dark-adaptation tests for vitamin A deficiency. In view, however, of the present large number of drivers who might be called upon to drive at night under emergency conditions—that is, A.R.P. ambulance drivers and drivers of fire engines and of cars for rescue squads and sitting cases—the question of a more accessible test is important. These people normally sit "on call" in a brightly illuminated room awaiting urgent summons into the often inky darkness outside.

I became interested in the problem because last December I was rather suddenly afflicted with night-blindness myself. After consultation with the A.R.P. officer, Mr. H. V. Casey, we called together the A.R.P. car drivers and tested them in the following manner: We used two long rooms in the Report Centre building, separated by a door containing a "hatch," such as police station inquiry offices often have, with a 10-watt bulb in the distant room and the hatch shut. The people to be tested were collected at the farthest end of the near room. Standing there with all the other lights out, the cracks at the top and bottom of the hatch showed just enough light to form a suitable test. Each candidate was made to stand watching the hatch for some sixty seconds in the full light of a 100-watt bulb in the centre of the room. This light was then switched off and the interval of time measured with a stop-watch until the cracks of light around the hatch became visible.

Eleven people were tested at the first sitting and gave the following readings in seconds: 5, 7, 8, 10, 11, 11, 14, 15, 20, 37, 56. Probably only the last had any true degree of night-blindness, but to be on the safe side the worst three were provided with halibut-oil capsules free. Re-tests have been done fortnightly ever since, taking the greatest care to have every detail of lighting, etc., exactly reproduced. At the next sitting the one with the 56-seconds reading had reduced her speed to 25 seconds, and there was no other reading above 21 seconds. Since then all drivers have been 20 seconds or less, except for one of 48 seconds and one of 82 seconds (myself). In both cases the culprits had for one reason or other failed for the preceding few days to take their ration of vitamin A.

A simple test such as this, practised widely, would avoid the two opposite disadvantages of (1) allowing night-blind people to remain undetected, a menace to themselves and the public, and (2) wasting money by issuing halibut oil to all, and also wasting the work of men who fish for halibut in the dangerous seas.—I am, etc.,

L. M. JOYCE HENRY.

Bedworth, March 25.

Vitamin B_1 in Diphtheria

SIR,—I should like to endorse the remarks made by Dr. Duncan Leys in his letter (March 29, p. 495) regarding the usefulness of vitamin B_1 in diphtheria and other toxic states. I have seen similar cases with gallop rhythm, vomiting, albuminuria, and diminution of urinary output during the second week of the disease, which appeared to respond rapidly to the administration of vitamin B_1 by intramuscular or intravenous injection.

There would appear to be need for further investigation into this subject, but the use of vitamin B_1 in cases of severe diphtheria would seem justifiable, to ensure complete oxidation of the large quantities of glucose usually given to such cases; at least until some simple deficiency test, similar to that used for vitamin C, becomes available.—I am, etc.,

HUGH CLEGG.

Kirkcaldy, March 31.

Cost of Vitamins

SIR,—It appears to me unfortunate that at a time when vitamin-containing foods are scarce the cost of vitamin preparations, which is always high, should be enhanced by purchase tax. I understand that the price of liver preparations has not been raised, and surely vitamin preparations should come into the same category, if, indeed, they are not subsidized by the Government so as to enable all to get them.

It would be interesting to know whether the gastric derangements found in the Army could be attributed, to any extent, to diminished vitamin intake, particularly of C. As we are told that black-currants are particularly rich in C it is to be hoped that some scheme will be devised for their preservation this summer, without sugar but with minimal destruction of the vitamin. Probably this would be best accomplished by factories using vacuum evaporation, but as this would involve much labour and transport, perhaps you would publish at an early date the best scheme for preservation by the country people themselves. This would be valuable even apart from the question of vitamin C, which may be solved by our American cousins.—I am, etc.,

Glasgow, March 31. J. MACEWEN.

Invalid Diet and Egg Shortage

SIR,—We are in complete agreement with the views expressed by Dr. Richard Bell in his letter. A possible source of increased rations for poultry or pigs could be obtained from a reduction in the amount of grain allowed for brewing and distilling. In the twelve months preceding the war 750,000 tons of grain and 450,000 tons of sugar products were used for these purposes. A 20% reduction would therefore save 150,000 tons of grain, sufficient to form half the food supply of 7 million head of poultry. We understand that recently a 10% cut has been made in the grain allowed and a 30% in the sugar. Would a further 20% reduction in the former be a hardship?

We are firmly of the opinion that the British working man, though he does not relish a reduction in his beer, would consent to the same if it were fairly put to him that the result would be an increase in the number of eggs avilable for the nourishment of his sick children.—We are, etc.,

N. I. SPRIGGS.
Leicester, March 31. S. E. TANNER.

SIR,—May I for one write in support of Dr. Richard Bell (March 22, p. 460) on the above most important question? The Ministry of Food publicly announced that eggs were not a vital food: that cheese (now unobtainable), dried peas, beans, and lentils were preferable. Those who understand dietetics know that the Leguminosae, valuable as they may be in their proper place, are the most indigestible of all articles of food and in no way a substitute for eggs in the diet of invalids, convalescents, and young children; the same applies to carrots and potatoes. Doubtless chicken feed is scarce, but surely the feeding stuffs given to that pampered animal the racehorse would do more to win the war if given to laying hens.

We should all heartily endorse Mr. Bell's last remark, which, we hope, will be noticed by the Council of our Association as worthy of suitable action.—I am, etc.,

S. H. FAIRRIE, M.B.,
Cheltenham, March 30. Lieut.-Colonel, R.A.M.C., retired.

Cyclical Mucosal Ulceration

SIR,—Dr. Prosser Thomas (March 15, p. 418) makes some interesting comments on my article (February 22, p. 271), and expresses the opinion that cyclical mucosal ulceration is due to a herpetic virus. In my article I mentioned that Kumer (1930 and 1932) had put forward the same idea but that the evidence is not very strong. Herpes is a condition capable of laboratory verification, and until this is done on a patient suffering from cyclical mucosal ulceration Dr. Prosser Thomas's view must remain merely a suggestion. Unfortunately I had not at my disposal the laboratory facilities necessary to prove or disprove such a conjecture.

What appears to me to be an important point against this herpetic theory is that the condition which I described is confined to mucous membranes, whereas the herpes virus, even if it involves mucous membranes, also affects skin at its junctions with mucous membranes if not elsewhere. I have seen a case, not published in my series, of a girl who suffered from dyspeptic symptoms associated with each cycle of buccal and vaginal ulceration. Gastroscopy on several occasions demonstrated similar ulcers of the gastric mucous membrane, which, after a few days, healed without scarring. Does the herpes virus ever involve the gastric mucosa? It is this restriction of the condition which I described to mucous membranes which appears to me to be an important argument against a herpetic aetiology. In the condition of catamenial herpes it is the skin of the lips and vulva and not the mucous membrane which is primarily and mainly affected. Catamenial herpes is a condition frequently mentioned by dermatologists, but gynaecologists make little or no mention of it. How common is the condition? I would like to have the opinion of gynaecologists in particular, as several have admitted to me that they have never seen a case of this malady.

Most students experience difficulty in mastering the fundamentals of medicine, mainly, in my opinion, because many "teachers" and medical writers use terms which they do not bother to define. This slipshod use of a vague quasi-scientific terminology infests much of our medical literature. The replacement of easily understandable English terms by Latin phrases is another slovenly habit to which many of our profession are addicted. Such translations never place a diagnosis on a more scientific footing.

Dr. J. Bernstien (March 8, p. 381) and Dr. B. Baneth (March 29, p. 494) suggest that cyclical mucosal ulceration is allergic. But allergic to what? Why do some medical men take such delight in suggesting that every condition of obscure aetiology is allergic? Dr. Baneth adds that "if the disorder is clearly associated with menstruation it might be classified amongst the menstrual molimina." I am not sure exactly what this means or how it helps. "Molimina," I suppose, is derived from the Latin noun "molimen," meaning "effort." Dr. Baneth states that because there was a familial incidence in some of my cases this suggests allergy. But how illogical to believe that because an unusual or exaggerated susceptibility to substances usually innocuous is often inherited any condition that exhibits a familial incidence suggests allergy as an underlying cause!

"Jevons, thou shouldst be living at this hour:
Medicine hath need of thee."

—I am, etc.,

Mitcham, Surrey, March 30. MALRICE H. PAPPWORTH.

Obscure Nervous Effects of Air Raids

SIR,—From time to time in your columns (and those of other journals) there have been references to shock, neurosis, etc., as a result of air raids. The general effect of these references has been to indicate a surprisingly low degree of nervous and shock response among the civilian population when subjected to heavy bombardment.

I am not a medical man, though trained as a biologist. I therefore write with diffidence on a subject about which I know little. But I have, on the other hand, had exceptional facilities for the observation of ordinary people during the past seven months of heavy raids. It has been my job to visit and report the after-effect of all the heavy raids and to follow up (with the assistance of a staff of investigators) the human results of the raids, both within the town attacked and in the surrounding areas affected by evacuation. It is the latter activity, the follow-up on evacuees—particularly "voluntary" evacuees—which has brought us up against the point I should like to put forward in this letter.

In widely separated areas, from Plymouth to Liverpool, from Coventry to Clydeside, we have come across several cases of persons who, after a heavy bombardment, have left next morning, found a billet with friends or relatives or strangers, and then caved in. In some cases they have simply taken to bed and stayed in bed for weeks at a time. They have not shown marked trembling or hysteria, but an extreme desire to retreat into sleep and into being looked after, as if chronically ill. We have found such cases mainly among women but also among men and children. We have not been

particularly looking out for the cases. Gradually, over a period of months, we have become impressed with the possibility that there may be quite a large number of them. They would not ordinarily be reported to a doctor at all, and tend to be regarded by the hosts as in the category of: "She's had a terrible time; what else can you expect?" Some general practitioners would probably treat the situation in much the same way. Certainly, such cases (partly because they do not conform with the ordinary pattern of neurosis and partly because they occur largely in small villages, etc.) are not likely to be reported to or to reach any psychiatrist. Yet they may be serious and even enduring reactions.

I am only raising this matter because it deserves further inquiry. I think it is conceivably misleading, even dangerous, when medical people look around the *cities* and in shelters, rest centres, and casualty wards, do not find the expected symptoms, and therefore go on to say that there is little nervous effect. The material conditions for potential neurosis in "blitzed" towns differ in many respects from any previous conditions. New types of reaction may be expected, and I believe are occurring; in particular, states of intense depression and retreat, without manifest physical symptoms. Such behaviour can have a profound effect on the morale of many others, as well as on the citizen capacity of the person directly concerned. I diffidently suggest that the matter might bear further thought and study.—I am, etc.,

London, W.11, April 1. TOM HARRISSON.

Plight of Consultants in Bombed Areas

SIR,—The position of members of the honorary staffs of hospitals in those provincial areas subjected to heavy bombing needs attention. Although some of the school children have been evacuated the bulk of the population remains; and the demand for ordinary hospital treatment is not less than before the war but more—in my case my wards are now spread over three hospitals (twenty-five miles apart) instead of one, and in addition E.M.S. routine treatment as well as the emergencies due to bombing have to be met. On the other hand, the wealthier members of the community have left, or at least have sent away their families; while heavy taxation has made a great inroad into the ability of middle-class patients to pay fees; and in either case all consultations and operations not absolutely *urgent* are "postponed." With the result that "income" has ceased to have any meaning for many consultants (I have made just £500 in a year, exactly the cost, with rigid economy, of running my practice).

What are we to do? Apart altogether from the feeling of loyalty to an institution that we have served for years, most of us are middle-aged, and can hardly be expected to resign appointments for which we have sacrificed patient years. We cannot obtain commissions, as the E.M.S. depends on us for its working. Yet the rewards from the latter are meagre—my cheque for sixteen months is under £40; and a major operation, including investigation, a fortnight's after-treatment, careful records, and a report with prognosis, brings in the fee of 11s. 6d. less income tax. Yet the medical services of the country depend on us, and we are apparently expected to provide them without any return at all: even if school fees, rent, and life insurance must be met from savings, the practice of eating cannot be entirely abandoned. In the London area those in a similar position get a retaining fee of £500 a year. The case for equal treatment of the Provinces seems unanswerable.—I am, etc.,

March 31. F.R.C.S.

E. A. Hines and N. W. Barker (*Amer. J. med. Sci.*, 1940, **200**, 117) made a clinical study of 280 consecutive cases of arteriosclerosis obliterans and a gross and histological examination of thirty-two legs amputated for this condition. The disease occurred mainly in men between the ages of 50 and 70. There was no significant difference in racial incidence. The pathological changes in the arteries consisted in (1) atheromatous plaques in the subintimal tissue, (2) degenerative changes in the medial coat, and (3) thrombosis. No variation of importance was noted in the lesions of arteriosclerosis obliterans among diabetic and non-diabetic subjects.

Obituary

We regret to announce the death on February 26 at Salisbury of Dr. WILLIAM ROBERT ORR of East Finchley. He studied medicine at Queen's College, Belfast, before the foundation of the University, and also in Dublin, graduating M.D. of the Royal University of Ireland in 1885, and M.Ch. and M.A.O. in 1886. Dr. Orr was in general practice for many years and became surgeon to the Finchley Memorial Hospital and medical officer to the local dispensary and maternity society. He joined the British Medical Association in 1899 and was chairman of the Finchley Division in 1927-8; he represented his Division at the Annual Representative Meetings in Bradford (1924), Eastbourne (1931), and London (1932).

Dr. WILLIAM FREDERIC CORY, a veteran Leeds practitioner, has died at his home in Headingley, aged 88. He was a student of the London Hospital and took the L.S.A. in 1874 and the M.R.C.S. in 1875. Among the appointments he held in former years at Leeds were those of honorary medical officer to the Jews' Mission and to the Gordon Boys' Corps, the Y.M.C.A. and the Y.W.C.A. Dr. Cory wrote several semi-popular booklets on sick diet and kindred subjects, and believed he could foretell the weather with a pocket spectroscope.

We regret to announce the death on April 3 in London, in his eightieth year, of Dr. M. HAJEK; late professor of laryngology in the University of Vienna. Prof. Hajek was a very famous teacher.

The Services

AWARDS AND MENTIONS IN DISPATCHES

The following awards have been made in recognition of distinguished services in the Middle East during the period August, 1939, to November, 1940:

O.B.E. (Military Division)

Lieut.-Colonels (Temporary Colonels) F. G. A. Smyth and Q. B. V. Wallace, M.C.; Lieut.-Colonel J. Melvin, M.C.; Majors (Temporary Lieut.-Colonels) A. O. Bekenn and J. M. Macfie, M.C., R.A.M.C.; and Major D. N. Chakravarti, I.M.S.

M.B.E. (Military Division)

Lieut. (Acting Captain) G. Lorriman and Lieut. H. R. Hartnell, R.A.M.C.

Mentions in Dispatches

Colonel (Acting Major-General) P. S. Tomlinson, D.S.O., and Colonel J. C. Sproule, O.B.E., late R.A.M.C.; Colonel (Acting Brigadier) A. J. Orenstein, C.M.G., S.A. Forces; Lieut.-Colonel (Acting Colonel) H. Alcock, Lieut.-Colonel D. C. Scott, O.B.E., Major (Acting Lieut.-Colonel) W. A. D. Drummond, Major (Temporary Lieut.-Colonel) F. R. H. Mollan, M.C., Captain (Local Lieut.-Colonel) R. P. Cormack (attached E.A.A.M.C.), Lieut. (Temporary Major) D. M. Blair, Captains J. MacMillan and J. B. M. Milne, and Lieuts. G. Geddes and J. B. Heycock, R.A.M.C.; Captain W. B. Stiver, I.M.S.; Jemadars B. D. Joshi and M. L. Varma, I.M.D.; Lieuts. (Local Lieut.-Colonels) S. W. F. Lee and C. H. Marshall, Lieut. (Local Major) D. Bell, and Lieut. A. C. E. Cole, E.A.A.M.C.

CASUALTIES IN THE MEDICAL SERVICES

ROYAL NAVY

In an Admiralty casualty list, published on April 4, Temporary Surgeon Lieut. LYON RAMSAY BLAIR, R.N.V.R., is posted as "Missing, Presumed Killed." He was the eldest son of the Rev. Dr. and Mrs. George Blair of Dundee, and was educated at the Morgan Academy, Dundee, and the University of St. Andrews. He graduated M.B., Ch.B. in 1931 and proceeded M.D. in 1940. He had held the post of casualty officer at Dundee Royal Infirmary, and was in partnership with Dr. George Bridge at Preston until November, 1939, when he joined the Royal Naval Volunteer Reserve. He had been a member of the British Medical Association since 1931.

ROYAL ARMY MEDICAL CORPS

Prisoner of War

Lieut. Joseph Gordon Kee.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

Part I of the Final M.B. Examination (surgery, midwifery, and gynaecology) will begin on Tuesday, June 17, and Part II (principles and practice of physic, pathology, and pharmacology) on Wednesday, June 18. Names of candidates should be sent to the Registrary by April 29.

UNIVERSITY OF LONDON

ROYAL CANCER HOSPITAL (FREE)

The following candidates have been approved at the examination indicated:

ACADEMIC POSTGRADUATE DIPLOMA IN MEDICAL RADIOLOGY.—*Part I:* I. H. Evans, C. K. Warrick.

UNIVERSITY OF EDINBURGH

The following candidates have been approved at the examinations indicated:

FINAL M.B., CH.B.—K. W. Beetham, J. F. Cameron, Frances C. E. Hutchison, A. F. Lang, Bertha Macfie (*née* Milne), W. A. T. M'Kendrick, A. K. M. Macrae, Joan M. M'William, T. M'I. Munro, E. J. Noble, M. R. Prestwich, Mary Scott-Wilson, J. G. Shearer, R. Taylor, C. C. MacD. Watson.

DIPLOMA IN TROPICAL MEDICINE AND HYGIENE.—E. Akwei, D. W. Horn, C. Odamtten-Easmon.

DIPLOMA IN PUBLIC HEALTH.—M. Nazir. *Part I:* Olive B. Barnetson, J. Cameron, W. Giles, Rachael Hunter, Margaret S. B. Langton, T. M. Small, Mona M. M'E. Thomson.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

SURGERY.—F. B. Beaver, G. R. S. Jackson, D. W. Mayman, R. South, A. M. Williams.

MEDICINE.—C. N. D. E. Eastes, R. South, C. H. Wood.

FORENSIC MEDICINE.—C. N. D. E. Eastes, R. South, C. H. Wood.

MIDWIFERY.—G. J. Ambrose, J. A. Dodds, J. S. McGillivray, R. South.

The diploma of the Society has been granted to F. B. Beaver, J. S. McGillivray, R. South, A. M. Williams, and C. H. Wood.

Medical Notes in Parliament

Fourth War Budget

Sir Kingsley Wood, Chancellor of the Exchequer, introduced the Budget on April 7. The standard rate of income tax is to be raised by 1s. 6d. to 10s. in the £, the tax on the first £165 of taxable income being raised from 5s. to 6s. 6d. Existing allowances are to be reduced as follows: earned income allowance from one-sixth to one-tenth with a maximum allowance of £150, and personal allowance for married persons from £170 to £140 and for single persons from £100 to £80. The extra tax paid because of these two reductions will be credited to the individual after the war in the Post Office Savings Bank, with a maximum credit of £65 for 1941–2. The exemption limit for both earned and investment income is reduced from £120 to £110. There are no changes in indirect taxation, but the Medicine Stamp Duty is to be repealed from September 2 next, and legislation introduced with the object of maintaining a fair balance between the interests of pharmacists and those of other vendors. The Chancellor stated that the prices of further essential goods and services are to be stabilized to prevent increases in the cost of living. The excess profits tax is to remain at 100%, but 20% will be refunded after the war for essential reconstruction and readjustment.

Science and War

In the House of Lords on April 2 Viscount SAMUEL asked whether the Government could make any statement on the extent to which the assistance of scientists had been enlisted in the prosecution of the war. He said that the council of the Institute of Chemistry had expressed the view that some of the Government Departments took too narrow a view of the term "scientist" and concentrated too much on professors from the universities and the like.

Lord HANKEY said that the three main pillars of scientific research were the Department of Scientific and Industrial Research, the Medical Research Council, and the Agricultural Research Council. They were all responsible to the Lord President of the Council. There were joint committees on matters of common concern, and contacts could hardly be closer. On the defence side there were research organizations in the Admiralty, the Ministry of Supply (which undertook most of the research work for the War Office), the Air Ministry (which had now handed over most of its research work to the Ministry of Aircraft Production), and the Ministry of Home Security (which occupied a position intermediate between the Service Departments and the Civil Departments). In addition there was a good deal of research in the Civil Departments. The Scientific Advisory Committee was in close touch through the Royal Society with the great streams of scientific research and development, through the representatives of Government research with Government activities, and through its chairman and the Lord President of the Council with the policy of the Government in these matters. He did not agree that the Government interpreted the term "scientific" rather narrowly. The reason for the non-inclusion of applied scientists on the committee was not a failure to appreciate their great importance in the war effort, but simply that the proposal did not fit into the Government conception of the Scientific Advisory Committee. The Government was at present in touch with the professional societies concerned with a view to the possible establishment of a separate organization working in the field of applied science and in close touch with the Scientific Advisory Committee. The committee had devoted itself mainly to the contribution of science to the war, and would continue to do so, but it was also in touch with the Minister Without Portfolio, who was in charge of reconstruction. The Directors of Scientific Research of each of the Departments engaged mainly in war work were invited in turn to tell the committee something of their activities. The Medical Research Council was concerned in all problems that affected man's health and efficiency. This Council, with its forty-five committees or subcommittees, its National Institute for Medical Research, and its nine smaller research units, brought an immense assistance to the war effort. Before the war, in concert with the Ministry of Health, preparations were made for safeguarding public health against the risks of war conditions. An Emergency Public Health Laboratory Service was established with laboratories all over the country so that unusual outbreaks of disease could be rapidly identified. Stocks of antisera and vaccines were distributed throughout the country and provision made for their replenishment. The Medical Research Council assisted the Defence Departments by increasing the efficiency and well-being of men who had to operate aircraft, tanks, and so forth. Good work had been done by a Flying Personnel Advisory Committee, which, at the request of the Admiralty, had been extended to the Navy. A Military Personnel Research Committee had been set up. The success of the Medical Research Council was largely due to its being given full scientific freedom and complete control over the funds at its disposal. The Scientific Advisory Committee of the Cabinet attached great importance to the use of the facilities of the Medical Research Council. This would probably be extended.

Medical Care of Auxiliary Territorial Service

On April 1 Captain MARGESSON informed Miss Ward that the facilities for treatment of sick members of the A.T.S. were comparable in all respects to those provided for soldiers. An eminent woman doctor had been appointed to the A.T.S. Council to advise on all medical questions affecting the Service.

Captain Margesson also circulated a detailed statement as follows: A.T.S. personnel who wish to report sick attend at the medical inspection room provided for the unit or detachment or nominated for use by the A.T.S. in any particular area, and can there receive out-patient treatment from the medical officer. To meet the needs of those who require more than out-patient treatment, reception stations are provided for detachments of 300 and upwards, and sick bays are opened at medical inspection rooms for smaller units. At reception

stations the medical officer, who may be a woman medical practitioner, has a staff including V.A.D. nursing members and members of the A.T.S., and may have a sister or staff nurse if required. A.T.S. orderlies are authorized in sick bays where the strength of the detachment is over forty. As regards hospital accommodation, a wing for A.T.S. patients has been established in one large military hospital, and there are A.T.S. wards in over twenty of the larger military hospitals. In addition, military families hospitals are used for the A.T.S., and all the hospitals of the Emergency Medical Service of the Ministry of Health are available for them. So far as convalescent treatment is concerned, there is an A.T.S. convalescent depot, and a Red Cross convalescent home is reserved for the use of women serving with the Forces. Courses of lectures in hygiene have been arranged as part of the training of officers and other ranks of the A.T.S.

New Rates of Pay for Nurses

In reply to a question by Miss Irene Ward on April 3 Mr. ERNEST BROWN said that the shortage of nurses in hospitals providing for the general needs of the civil population, and in particular for infectious diseases and the old and infirm, was giving rise to anxiety. Available beds could not be used because of the shortage, and staffs were carrying on under increasing difficulties. He was appealing to women and girls to enrol for nursing service in any part of the country. Those who joined as nursing auxiliaries would not be sent to hospitals dealing with infectious diseases or mental cases or to sanatoria unless they volunteered for this service. Women who were prepared to take up nursing as a life career and to enter as student nurses one of the hospitals recognized as training schools would receive salaries at the rate of £40 a year, rising by annual increments of £5.

The salaries of members of the Civil Nursing Reserve in residential posts in hospitals were to be increased. Those of the assistant nurse and trained nurse included a sum representing the employer's contribution towards superannuation, and as from the first pay week in February the rates would be: nursing auxiliaries £55 a year, assistant nurses £70 a year, trained nurses £105 a year, with board, lodging, and laundry, and indoor and outdoor uniforms. Those who responded to the appeal and were accepted would receive a guarantee of a year's employment and would be asked to undertake to serve for that period. Recruits who joined as nursing auxiliaries would receive a short course of instruction in hospitals, during which they would receive 10s. a week as pocket-money, together with board, lodging, and laundry.

The Government had accepted the recommendation of the Athlone Committee that a Salaries Committee analogous to the Burnham Committees in the teaching profession should be established. The work of fifty-three State-registered nurses on the staff of the Ministry at Headquarters and in Regional offices, who were partly recruited for the E.M.S. services and partly for the public health and hospital work of the Department, would be grouped on its professional side into a Nursing Division of the Ministry under the general direction of a Chief Nursing Officer (Miss Katherine Watt) with two deputies.

Mr. Brown added that he had asked Miss Horsbrugh to make the Nursing Division her special concern. Mr. Johnston was making similar arrangements subject to such minor modifications as the conditions in Scotland required.

Increase in Scabies

Mr. ERNEST BROWN said on April 3 that there had been an increase in the incidence of scabies. Advice about the prevention and treatment of this disease had been given to local authorities, and their attention drawn to the importance of actively pursuing preventive measures under wartime conditions. Similar advice had been given in the leaflets and advertisements put out by the Ministry and the Central Council for Health Education. Further consideration was being devoted to the subject.

Notes in Brief

The number of medical officers employed by the Ministry of Health, including hospital staff under the Emergency Medical Service and officers on loan to other Departments or serving with the Forces, is 147, of whom fifty-two are serving in a temporary capacity. Sixty-three are employed in London.

EIREANN MEDICAL MISSION

A medical mission appointed by the Eireann Minister of Defence, which has come to London to study civil defence arrangements, was welcomed at the Ministry of Health on April 1 by Mr. Ernest Brown, Minister of Health, who was accompanied by Sir Weldon Dalrymple-Champneys, deputy chief medical officer at the Ministry. The mission, which is headed by Commandant Patrick J. Delaney, comprises nine surgeons and physicians. The members were presented to Mr. Brown by Mr. John Dulanty, High Commissioner for Eire. The mission will investigate medical problems arising out of evacuation and visit some of the reception areas. It will study the steps which are being taken by the United Kingdom Government to guard against the spread of infectious disease, and also examine the arrangements for maternity homes, first-aid posts, ambulance services, base hospitals, medical supplies, and blood transfusion. The Ministry of Health is providing full facilities for the mission's tour of inspection.

Medical News

There is an urgent demand for specialists in ophthalmology for the R.A.M.C. and the R.A.F.V.R. Any ophthalmologist who is prepared to offer his services and who feels that he can be spared from his locality is requested to communicate with the Secretary of the Central Medical War Committee, B.M.A. House, Tavistock Square, London, W.C.1.

The British Social Hygiene Council requires a part-time Medical Secretary to visit the Provinces and give lectures. Familiarity with social hygiene questions and interest in the sex education of adolescents are desirable. Particulars may be had from the Secretary-General of the Council, Tavistock House South, W.C.1.

At the next meeting of the Shaftesbury Military Hospital Medical Society, on Tuesday, April 15, at 3 p.m., the address will be given by the president, Major-General F. Casement.

The next meeting of the North-Western Tuberculosis Society will be held at the Tuberculosis Offices, 352, Oxford Road, Manchester, on Thursday, May 8, at 3 p.m., when Dr. S. Vere Pearson will speak on "What are we aiming at in Collapse Therapy?"

Dr. Cyril James, Principal of McGill University, Canada, suggested recently that the Colonial Office might regard it as a contribution to the war effort if McGill were to establish a School of Tropical Medicine to carry on the work of the London School, which was believed to have been temporarily interrupted. Telegraphing his "grateful acknowledgment of this very kind offer," however, the Secretary of State for the Colonies, Lord Moyne, was able to assure Dr. James that he had been informed that teaching is being carried on effectively at the London School in spite of present circumstances, and that it is not anticipated, unless conditions become much worse, that assistance on the lines indicated would be needed.

Steel helmets are now to be issued on loan free of charge to domestic staff of a hospital working full time but living out, doctors and nurses regularly employed in public air-raid shelters, members of the Civil Nursing Reserve employed as assistants to district nurses, nurses employed in auxiliary hospitals, and members of V.A.D. and ambulance organizations who have to work in the open or have to travel during air raids. The number issued will be limited to that required to carry out the particular service efficiently. Helmets may also be purchased with the aid of the appropriate grant for volunteers regularly employed in ancillary services.

Dr. W. F. Rhodes, professor of medical jurisprudence at the University of Capetown and senior pathologist of the Union Health Department, has been appointed as the representative of the university in the Leprosy Advisory Council.

Dr. E. D. Friedman has been appointed Director of the Department of Neurology at the New York University School of Medicine.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

The common infectious diseases are fluctuating in incidence without showing any definite downward or upward trend. Measles showed a drop of 368 on the previous week's figure, but increases have been returned from several areas, and figures for Dorset, Essex, Middlesex, and Warwickshire have increased for two consecutive weeks. The increase for Dorset, 31, has been fairly general throughout the county; the rise in Essex, 307, came from the urban areas; the rural districts were responsible for the increase in Warwickshire, 127. Edmonton U.D., where the number of notifications rose from 55 to 150, was responsible for the increase shown by Middlesex, 99. The decrease in notifications of measles in Scotland, 41, was general: the only area reporting an increase was Dundee, where 8 more cases were notified than in the preceding week.

Whooping-cough

The figure for whooping-cough in England and Wales shows a fall of 279, but increases for two consecutive weeks have been reported from several areas: for the counties of Durham, Essex, Leicestershire, Middlesex, and Oxfordshire notifications almost doubled during the two weeks March 1–15. The incidence was fairly widespread throughout the country, but in some counties the disease has been concentrated in the county boroughs. The chief instances are: Lancashire 828, Liverpool C.B. 156; Leicestershire 120, Leicester C.B. 81; Northumberland 99, Newcastle C.B. 45; Oxfordshire 66, Oxford C.B. 54; Warwickshire 197, Birmingham C.B. 126; Yorks (East Riding) 38, Kingston-upon-Hull C.B. 27; Yorks (North Riding) 48, Middlesbrough C.B. 30. A further rise in the number of cases of whooping-cough has occurred in Scotland, where an increase has been reported every week since February 8. Three-quarters of the notifications are from Glasgow—653 out of the 868.

Diphtheria and scarlet fever have slightly increased in England and Wales but decreased in Scotland and Ireland. Leicester C.B. has returned an increase of 19 cases of both these diseases.

Dysentery

The number of cases notified showed a further, but small, decrease. The outbreak in Biggleswade R.D. with 21 cases, for the week ending March 15 continues to be the most notable of the localized epidemics. The returns for Colchester M.B. for the last two weeks, 10 and 8 cases, suggest that the rather serious outbreak in this area is over; 177 cases have been reported from this town in the last seven weeks. Lancaster M.B., with 11 cases compared to 6 in the preceding week, is now one of the principal centres of the local outbreaks. Fresh centres of infection appeared during the week and multiple cases have been recorded from Cambridgeshire, Chesterton R.D. 6; Dorset, Dorchester R.D. 4; Kent, Dartford R.D. 7; East Sussex, East Grinstead U.D. 4. The London figures show an increase of 9 on the previous week's total; more than one case was recorded in: Chelsea 6, Hackney 2, St. Marylebone 5, Shoreditch 3, Wandsworth 2.

Cerebrospinal Fever

A decrease occurred in the incidence of cerebrospinal fever in England and Wales during the week. In Essex 14 cases and Warwickshire 23—in both instances an increase of 9 on the notifications for the preceding week—were returned. In the latter county the increase was mainly confined to Birmingham C.B., where the numbers rose from 10 to 16. Yorks (West Riding), 29 cases, returned 7 more cases than in the previous week.

Quarterly Returns of the Registrar-General

The returns for the thirteen weeks ended September 28, 1940, now published, show a death rate of 10.9 per 1,000, compared with an average of 9.8 in the third quarter of the five preceding years. The birth rate was 14.3 per 1,000; the average for the third quarters of the five preceding years was 15.3. Infant mortality was 42 per 1,000 live births, three below the average of the ten preceding third quarters. Stillbirths represented 3.5% of the total births registered.

No. 11

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended March 15, 1941.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1941 (a)	1941 (b)	1941 (c)	1941 (d)	1941 (e)	1940 (Corresponding Week) (a)	1940 (Corresponding Week) (b)	1940 (Corresponding Week) (c)	1940 (Corresponding Week) (d)	1940 (Corresponding Week) (e)

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

Authors desiring REPRINTS of their articles must communicate with the *Secretary, B.M.A. House, Tavistock Square, W.C.1, on* receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE NO.—B.M.A. and *B.M.J.*: EUSTON 2111.

TELEGRAPHIC ADDRESSES.—EDITOR, *Aitiology Westcent, London*; SECRETARY, *Medisecra Westcent, London.*

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

QUERIES AND ANSWERS

Treatment of Snoring

MR. HAROLD CHAPMAN, L.D.S. (London, W.1), writes: In reply to Dr. George Macdonald (February 1, p. 182), the following letter is taken from the *British Dental Journal* of November 15, 1940: "If the nares are free, a mouth valve, with the addition, if necessary, of a support for the chin, should make snoring impossible.—Yours faithfully, J. H. BADCOCK." In reply to another letter asking what a mouth valve is I wrote privately the following to my correspondent: "A mouth valve—screen is a better term, because its object is only to close an opening, the mouth—is a piece of material which lies between the lips and cheeks on one side and the gums and teeth on the other, to prevent air entering the mouth; it also prevents air leaving. It is made on a model made from an impression of the area taken in one piece and the teeth closed: it extends to the bottom of the sulci and back as far as the second premolars or first molars: it may be attached to the clothing by a piece of silk which passes through two pinholes in the screen." The material used is usually aluminium or celluloid: the screen is worn during sleep. Dentists make these for their patients to prevent mouth-breathing as well as snoring: they are also used in the correction of irregularities of the teeth.

Sjögren's Syndrome

A READER writes: Dr. Colls can find a full account of Sjögren's syndrome in Sjögren's article on the subject in *Modern Trends in Ophthalmology*, edited by Ridley and Sorsby, London, 1940, p. 403. Medication by thyroid extracts and vitamin A might be useful.

Income Tax

Premiums for Superannuation Benefit

"J. J." has two policies, under each of which he pays a premium of £75 to secure a deferred annuity. There is no capital sum payable at maturity or death. Is he entitled to an allowance for the full amount paid—i.e., £150?

*** No. Section 32 of the Income Tax Act, 1918, provides that an allowance for premiums paid for benefits other than payment of a capital sum shall not exceed "the amount of the tax calculated at the appropriate rate on £100." "J. J.'s" allowance must therefore be calculated as if his total payment were £100 only, and not £150.

LETTERS, NOTES, ETC.

Tuberculosis in the Navy: Corrigendum

Surgeon Rear-Admiral SHELDON F. DUDLEY, F.R.S., writes: In the report of my paper on tuberculosis in the Royal Navy appearing in your issue for April 5 there is a serious error in the abstract of the statistics near the bottom of page 531. The last two columns are incorrect. The table should have read:

	Re-examined (Full-size Radiograph)	Percentage Re-examined	? Active Tb. No.	? Active Tb. per 1,000
Trained men ..	269	4.0	31	4.5
New entrants ..	403	3.4	38	3.2

The matter is important, as the last column is a rate per 1,000, not a percentage; it also is of "suspected to be active" and *not* "established" progressive cases. As the figures were printed they made the amount of concealed pulmonary tuberculosis to be fifteen times as great as what was actually found in these groups of naval ratings.

In Gratitude to Medical Colleagues

MR. G. H. STEELE, M.S., F.R.C.S. (Guildford) writes: The Honorary Treasurer of the R.M.B.F. (March 29, p. 500) quotes the letter of a doctor who sent a donation to the Fund as an expression of his gratitude for treatment by colleagues. In doing this he makes a very helpful suggestion to all medical men who, as happens to most of us, are faced with the embarrassment of refusing to take a fee from a doctor patient or his dependants, who are uncomfortable if they feel they are trespassing on one's time. The situation is frequently overcome by a personal gift, but when the patient is embarrassed by accepting services without being able to pay, to suggest a thankoffering to the R.M.B.F. is surely the solution. I can recall several cases where such a suggestion would have made the patient easier in mind, and intend to follow this course in any such cases in future.

Adrenaline in Shock and Fever

DR. J. BARCROFT ANDERSON writes: There is one point in the paper of Drs. Bywaters and Beall (March 22, p. 427) on what they describe as crush injuries to which reference has not yet been made in your pages. They wrote: "The effect of adrenal cortical extract in this condition should also be observed." May I suggest that adrenaline chloride solution 1 in 1,000 every four hours by the mouth, in water, be tried. When treating bubonic plague in 1905 (*Lancet*, 1910, 1, 994) I found that its effect, so given, on constricting the pulse was almost immediate and lasted exactly four hours. My greatest dose in that disease was half a drachm. Sir Edward Thornton's obviously greater success in treating plague in 1907 was, I think, due to his giving larger doses of medicine. My treatment of the sick ended in 1925, and then ended my opportunity to study further the uses of adrenaline. In a case of haemorrhagic small-pox in a man aged 72, who for a week showed no sign of improvement, four-drop doses of adrenaline every four hours were followed by rapid recovery. In a case of enteric fever, beginning with delirium and with continued refusal to speak or swallow, four drops of adrenaline with some mineral acid were added every four hours to what went down an oesophageal tube. After some days this was discontinued, with an immediate rise in temperature of 1° F. When the adrenaline was resumed the temperature fell that degree. I have studied the adrenals in over 500 inquests. Where death was immediately preceded by shock or by acute fever from pathogenic germs the medulla was dark brown and so soft that the adrenal could be as easily inverted as the finger-tip of a thin kid glove. If there had been continuing illness due to a germ the adrenal was pale throughout and its cortex greatly thickened.

Scientific Films

Seven films were shown recently at the Polytechnic Cinema by the London Scientific Film Society, all of them relating to individual or communal health. "Men of Medicine" in the "March of Time" series, although not a new film, gives an interesting picture of the life of a doctor from student days to busy general practice, and includes a glimpse of the American Medical Association in session. "Health in War," produced by the G.P.O. Film Unit, records such changes in our wartime health services as the evacuation of children, the Emergency Medical Service in operation, and a special hospital working in a country environment. The scientific critic can find no fault and the lay spectator no dull minute in the life-story of the malarial parasite as shown in "Malaria" with some excellent photomicrography and also diagrams of the processes in the blood stream. The Ministry of Information has two new films: "We Have to Get Rid of the Rats," in which a rat-catcher supplies the commentary, and "The Red Army," showing how bed-bugs live and how they can be exterminated. "Land without Bread" is a French film, set in an isolated community on the borders of Spain and Portugal, and depicts the consequences of a diet for generations of potatoes and beans with wild cherries in the summer. Finally, in "Heredity in Man," in which the commentator is Prof. Julian Huxley, a difficult subject, and one which does not lend itself to the generalizations on which propagandist film technique depends, has been handled with care and discrimination.

National Union of Students Congress

The Hon. Secretary of the Middlesex Hospital Common Room Society writes to say that at a meeting of this society the students decided that a delegate should not be sent to the forthcoming National Union of Students Congress at Cambridge, and that formal notice of resignation be given to the Union. The main reason for this was that in the opinion of the society the activities of the medical subcommittee of the Union no longer retained a non-political character.

Messrs. John Bartholomew and Son, Ltd. (66, Chandos Place, London, W.C.2), have added a map of North-East Africa to their General World Series; the price, printed on paper, is 2s. 6d. net.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY APRIL 12 1941

MEDICAL MAN-POWER

ALLOCATION BETWEEN CIVILIAN AND MILITARY SERVICES

The memorandum on allocation of medical man-power between civilian and military services, reproduced in an abridged form below, was issued by the Ministry of Health on March 28 to the medical officer of health of each county and local authority, to voluntary hospitals in the Emergency Hospital Scheme, and to other bodies concerned. The Circular is numbered 2323.

The steady expansion of the Armed Forces at home and over-seas has led to a growing need for doctors in the medical branches of the Royal Navy, the Army, and the Royal Air Force, which has recently been examined by the Ministers concerned in relation to the medical needs of the civilian community. This examination has made it apparent that further special measures are necessary on all hands if the limited numbers of doctors available are to be employed to the best advantage on work which as a whole much exceeds that falling on members of the profession in time of peace.

Service Needs

Accordingly, the three Service Departments are reviewing all their medical establishments, and it is hoped thereby to reduce in a number of ways the further calls that would otherwise have to be made on the doctors remaining in civilian practice in this country. The needs of the different theatres of war, however, are so great that such calls will still have to be made from time to time, which will be met as hitherto from practitioners liable to military service, through the machinery of the Central Medical War Committee appointed to advise the Government on these matters.

Review of Emergency Medical Service

The Minister for his part is reviewing the Emergency Medical Service with the intention of releasing for the Armed Forces a number of whole-time and part-time members now enrolled in it, (i) by reducing the present strength of the E.M.S. and (ii) by replacing, in addition, a number of British members by the enrolment of foreign practitioners admitted to practice under the Medical Register (Temporary Registration) Orders.

Review of Other Hospital Staffs

In the view of the Government, hospital authorities should take all possible steps in the same directions in relation to their own medical staffs. The Central Medical War Committee is inviting them to review the existing establishments of A, B2, and B1 resident posts with a view to considering the possibility of reducing them, and the Minister emphasizes that this recommendation has his support and urges hospital authorities to extend their review to any senior posts outside these three categories. In addition to savings in staff secured in this way, hospital authorities have been asked to consider favourably the employment of foreign practitioners recently facilitated by the Medical Register (Temporary Registration) Orders so as to release the British practitioners they replace for service with the Armed Forces. In the case of doctors of enemy nationality certain restrictions apply.

Replacement of House Officers by Senior Students

The Minister is also of opinion that the time has now come, as in the last war, to employ senior medical students in their final year of study on the duties of junior house officers (A posts) so far as is compatible with the law. By this means a number of present holders of A posts will be freed to perform duties now carried out by senior house officers (B2 posts) or junior medical officers (B1) who can be released for the Medical Branches of the Armed Forces. In the interests of medical education and to maintain a proper standard of efficiency of treatment students should be employed in this way only in hospitals where adequate supervision of their work by members of the teaching staffs of the medical schools would still be available. It is considered inadvisable to replace more than 50% of the junior house officers by students in this way. It is suggested that normally the students selected for these appointments should hold them for three months only, but the exact arrangements will depend on the ratio between the number of senior students in the medical school and the number of house appointments filled from that school, and upon other local conditions.

Practically all hospitals which will be able to employ senior students in this way are included in the Emergency Hospital Scheme, and financial arrangements for honoraria and for board and lodging have been made in respect of those so employed in voluntary and in municipal hospitals.

Mobility of Hospital Staffs

As the shortage of doctors makes it impossible for every hospital to be staffed up to the optimum standard at all times it becomes more important than ever to apply the principle of mobility of medical staff which has been inherent in the Emergency Hospital Scheme from the outset. In considering action under the circular, hospital authorities should feel that every hospital in the scheme is a unit in a comprehensive organization, and that they should therefore help each other and be able to rely on each other, in times of special stress, by lending or borrowing medical staff. Practitioners enrolled in Class I or Class II of the E.M.S. are at the disposal of the Ministry's Hospital and Group Officers for this purpose and have been transferred from time to time to hospitals faced with a special emergency, but the same principle should be freely extended by hospital authorities to medical staff in their own employment, on the analogy of the arrangements for mutual aid and reinforcement which form an important part of other Civil Defence Services.

In particular, the services of additional junior house officers (holders of A and B2 posts) are often invaluable for relieving temporary pressure upon hospitals, and the Minister hopes that every hospital authority will readily comply with requests it may receive from time to time from Hospital or Group Officers to lend its staff temporarily. He has refrained from enrolling holders of A and B2 posts in the E.M.S. in order that hospitals may enjoy full liberty of action to move junior house officers from one kind of work to another in the interests of their further education, and in order to facilitate a proper flow of newly qualified men into hospital establishments.

Public Health Medical Staffs

In view of the varying conditions of different parts of the country, and the change arising from evacuation and other large-scale transfers of population, no general direction can usefully be given in regard to the possibility of releasing members of public health medical staffs not holding hospital appointments. The Minister hopes that each authority will consider the question in the light of the circumstances of its area, and the Principal Regional Medical Officer has been instructed to confer in the matter with the M.O.H. It is not intended to suggest the release of officers where their removal would prejudice the maintenance of some essential health service, but each of these services should be reviewed with a view to effecting the maximum economy in man-power. For example, the employment of an available woman practitioner on maternity and child welfare work, and the transfer of other functions to a general practitioner over military age who

is able to spare an adequate proportion of his time from his private practice, might enable the authority to release a young member of its medical staff for service with the Forces. In some areas it may be possible to share the work of medical officers of health and their assistants between officers of different local authorities to a greater extent so as to spread the work over a smaller number of officers. Administrative and clerical duties not requiring to be directly performed by a medical man should be delegated to lay staff.

The various measures outlined in this circular should provide a substantial number of practitioners suitable for service in a medical capacity with the Armed Forces. Private practice has already been seriously affected by the recruitment of practitioners of military age, and, if a fair balance is to be preserved and essential medical services carried on, other branches of medical practice ought to make further contributions to the Armed Forces. The Minister relies upon public health and hospital authorities to co-operate in meeting this urgent national need.

E.M.S.: Payment for Referred Service Cases

The Ministry of Health has found it necessary to define still further the circumstances in which a medical practitioner is paid £1 1s. for conducting a special investigation or giving a second opinion on Service casualties or sick referred to hospital out-patient departments. Circular 2326, which has been sent to local authorities and to E.M.S. hospitals, points out that it was intended that cases should be sent direct to out-patient departments by military medical officers with a written diagnosis on which a second consultant opinion would be required, and that after the examination the patient would be returned to his unit along with, or followed quickly by, the report. It was not intended that payment should be made for cases referred to out-patient departments from other hospitals or for cases sent by military units for out-patient treatment only. Nor was it contemplated that in every case where patients attended for investigation for which *x*-ray treatment was necessary the examinations would invariably be regarded as special investigations, although it was recognized that there were circumstances in which cases might qualify for payment—for example, when a clinical examination was necessary. Hospitals are, therefore, asked to exercise special care before making the payments to satisfy themselves that these conditions have been properly observed, and to avoid submitting incorrect claims should ensure that all the cases are fully in accord with the intention of Circular 2176 to remunerate medical staff for consultative "second opinion." To enable the Department to be satisfied that the claims may be properly admitted the following particulars of each case should be submitted with Form A.G. 136: (1) The date of the examination. (2) The name, number, rank, and unit of the patient. (3) The name of the Army medical officer from whom, and the place from which, the patient was directly and specially referred. (4) The name of the hospital consultant carrying out the examination to whom the guinea was paid. (5) A brief note of the diagnosis.

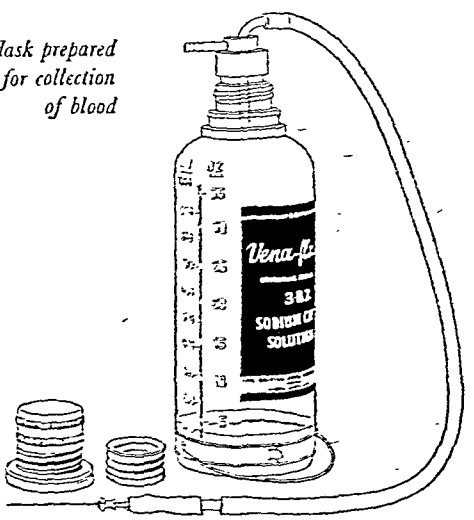
Sealed Vena-flask

Vena-flasks

for Intravenous Infusions and Blood Transfusions



The Vena-flask and accessories have been scientifically designed to give the utmost ease and simplicity in use. The triple sealing prevents any possibility of contamination.

Intravenous Solutions in Vena-flasks are prepared with pyrogen-free distilled water and chemical substances of the highest degree of purity. Samples from every batch are tested for sterility and for suitability for intravenous use before issue.

Apparatus assembled for the intravenous administration of fluid

Vena-flask prepared for collection of blood

A booklet entitled "The B.D.H. Vena-flask and its use in Intravenous Therapy" will be supplied on request.

SURGICAL SERVICE
SALTAIR

Pleases Patient and Practitioner

SALT'S
ENTEROPTOSIS BELT

DESIGNED BY A MEDICAL MAN

Salt's Enteroptosis Belt pleases the patient by the simplicity of its design and its inherent good style. At the same time it pleases the Practitioner by reason of its real efficiency in giving adequate support to the lower abdomen in particular. Fastenings are reduced to a minimum, yet there are ample facilities for adjustment as and when required. Shaping at sides holds the belt well down without perineal straps. This Belt is described at greater length in Salt's Corset & Belt Book—post free to any Doctor upon request. This is the book with the handy Measure/Order forms.

Guarantee
"We guarantee to alter exchange or accept the return of any appliance without cost ordered by the Medical Profession, if not found Suitable within fourteen days from date of supply."

SALT & SON LTD · BIRMINGHAM 4

for rapid hæmostasis . .

TRADE MARK **'STYPVEN'** BRAND

RUSSELL VIPER VENOM

(not for injection)

'Stypven' Russell Viper Venom possesses remarkable hæmostatic properties, is quickly prepared and acts rapidly. It is indicated in

Hæmorrhage due to superficial injuries and after tonsillectomy

External bleeding of hæmophilics

Nasal and oral surgery, used alone or in conjunction with Adrenaline

Epistaxis

Dental extractions in patients prone to hæmorrhage

Gum-margin bleeding

Hæmorrhage control during anæsthesia

'Stypven' is issued in rubber-stoppered bottles accompanied by hermetically-sealed ampoules of solvent (sterile distilled water containing 0·5 per cent. phenol). A fresh solution of the necessary concentration is thus quickly prepared for emergency use.

Trade Mark **'STYPVEN'** Brand Russell Viper Venom (not for injection)

Containers of 1 c.c. (0·1 mgm. venom and solvent) and containers of 5 c.c. (0·5 mgm. venom and solvent) 1/4 and 2 8 each respectively.

THE SAFEST AND MOST SUCCESSFUL CONTRAST MEDIA FOR PYELOGRAPHY

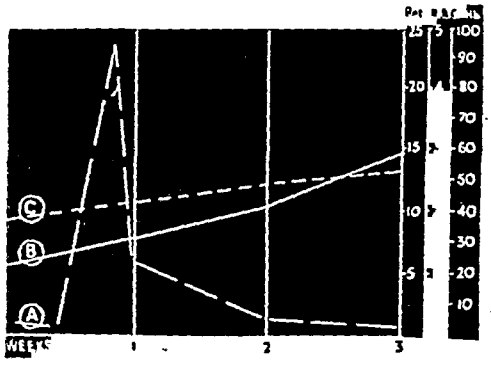
PRODUCTS OF THE GLAXO LABORATORIES

PYELECTAN
Brand of IODOXYL INJECTION

For intravenous pyelography. Each 20 cc. ampoule contains in aqueous solution 15 gm. of the disodium salt of 3:5-di-iodo-4-pyridoxyl-N-methyl-2:6-dicarboxylic acid (Iodoxyl). Gives dense, defined shadows. Ampoules in boxes of 1 x 20 cc., 10/6; 5 x 20 cc., 52/6; 1 x 3 cc., 2/6.

PYELECTAN (Retrograde) For instrumental pyelography. Each 10 cc. ampoule contains in aqueous solution 2 gm. of the above compound, with 0.1 mg. of mercuric oxycyanide.
10 cc. ampoule, 3/6.

PYELOSIL
Brand of DIODONE INJECTION



For excretion pyelography and other radiological examinations. Each 20 cc. ampoule contains in aqueous solution 7 gm. of the di-ethanolamine salt of 3:5-di-iodo-4-pyridone-N-acetate (Diodone). For intravenous injection, or can be given subcutaneously when a suitable vein cannot be found. No sloughing follows if 'Pyelosil' escapes into the perivenous tissues. Ampoules in boxes of 1 x 20 cc., 10/6; 5 x 20 cc., 52/6; 1 x 3 cc., 2/6.

Special literature for all the above preparations is available on request. All prices are subject to usual professional discount.

Easing the burden of life-long treatment for Pernicious Anaemia

Examen Liver Extract provides the physician with the means not only of quickly restoring the patient's normal blood picture, but of securing the *most effective maintenance treatment with the minimum of discomfort and expense to the patient.* Each 2 cc. of Examen is derived from 100 gm. of fresh liver. Such concentration of the erythrocyte maturing factor maintains normal hæmopoiesis with small, widely spaced doses, e.g. 2 cc. every 3 to 5 weeks. The exceptional purity of Examen and its freedom from protein render injection painless and ensure absence of undesirable reactions.

A—Ret.—Reticulocytes (per cent. R.B.C.)
B—R.B.C.—Red blood corpuscles (millions per cmm.)
C—Hb.—Haemoglobin (per cent)

The graph (an example of an actual case) indicates how Examen gives the required reticulocyte response, followed by a rapid regeneration of red blood corpuscles and the restoration of the hæmoglobin level.

PROTHROMBIN DEFICIENCY IN DISEASE OF THE LIVER AND BILE PASSAGES AND ITS TREATMENT WITH SYNTHETIC VITAMIN K

BY

JAMES REID, M.B.

McCunn Research Scholar, University of Glasgow

(From the Gardiner Institute of Medicine, in the University)

Prothrombin deficiency as a cause of haemorrhage in disease of the liver and bile passages has attracted attention in recent years and has resulted in an important therapeutic advance. A brief account of the development of this work may be given before reporting the results of the present investigation. Dam (1934) and Dam and Schönheyder (1934), while working on a problem of fat metabolism, noticed that chicks fed on a fat-free diet soon developed subcutaneous and intramuscular haemorrhages, which they showed were associated with a deficiency of prothrombin in the circulating blood. They observed that cure was obtained by adding green vegetables to the diet, but that it did not follow addition of the known accessory food factors. Thus a new dietary substance was demonstrated which had the power of increasing the amount of prothrombin in the blood when it was deficient. This new factor was found to be fat-soluble, and was named vitamin K by Dam after the initial letter in the Danish word "Koagulation." Quick and his colleagues (1935), working in America, observed prothrombin deficiency in the blood of patients suffering from severe obstructive jaundice. A link between these two observations was soon demonstrated by Butt *et al.* (1938), Brinkhous *et al.* (1938), and Dam and Glavind (1938) when it was shown that prothrombin deficiency and haemorrhage in obstructive jaundice could be prevented by administering ether extracts of alfalfa grass. This work was at once recognized to be of practical value in the surgery of obstructive jaundice, and was confirmed in America by Stewart and Rourke (1939) and in this country by Illingworth (1939a).

Studies on the constitution and properties of vitamin K were undertaken in Denmark and America. It was early recognized that a naphthoquinone group formed part of the molecule (MacCorquodale *et al.*, 1939); hence various naphthoquinone preparations were used in the treatment of prothrombin deficiency in obstructive jaundice. Of these preparations a water-soluble compound, phthiocol (2-methyl-3-hydroxy-1:4-naphthoquinone), given intravenously, was found to have some activity (Butt *et al.*, 1939), but was apparently not so potent as water-insoluble 2-methyl-1:4-naphthoquinone, injected intramuscularly or given by mouth in conjunction with bile salts (Almquist and Klose, 1939; Macfie, Bacharach, and Chance, 1939). After the active principle of the vitamin had been isolated and its constitution found to be 2-methyl-3-phytyl-1:4-naphthoquinone (Binkley *et al.*, 1939; Fieser, 1939), it was shown that 2-methyl-1:4-naphthoquinone was at least as potent as the vitamin itself (Ansbacher *et al.*, 1939).

Quantitative Estimation of Prothrombin in Blood

Prothrombin is considered to be a pro-enzyme associated with the globulin fraction of the plasma proteins. It is destroyed by heating blood to 60° C., and may be removed from plasma by adsorbing agents (Quick, 1940). It is believed to be formed by the liver, since the amount in the blood diminishes when the liver is severely damaged, as in acute cytolytic necrosis and in chloroform poisoning (Smith *et al.*, 1937), or when it is partially excised in dogs (Warner, 1938). The only known function of prothrombin is the formation of thrombin in the presence of calcium and thrombokinase, the latter being derived from platelets and tissue juice. Thrombin coagulates fibrinogen, forming fibrin. The velocity of this reaction bears a definite relation to the concentration of thrombin present: thus with small amounts of thrombin the coagulation time is prolonged; with large amounts it is shortened. Hence the time taken for the coagulation of a sample of blood in which adequate amounts of calcium, thrombokinase, and fibrinogen are known to be present will be an index of the amount of thrombin and so of the amount of prothrombin originally present. This coagulation time has been termed the "prothrombin time" (Quick, 1935), and is used as a criterion for the quantitative determination of prothrombin in blood. During the coagulation of blood two reactions are considered to occur, and may be represented thus: (1) prothrombin + calcium + thrombokinase → thrombin; (2) thrombin + fibrinogen → fibrin.

The prothrombin time includes both reactions, and objection may be raised that variations in the speed of the first reaction might vitiate the test as an index of the amount of prothrombin present, but in practice this has not caused any difficulty in my work. It is unnecessary to estimate the amount of fibrinogen in each sample of blood, since quantities insufficient for coagulation are seldom encountered.

Method of Determining the Prothrombin Time (Quick *et al.*, 1935, modified).—4.5 c.cm. of venous blood is taken

into a syringe containing 0.5 c.cm. of M/10 sodium oxalate. After centrifuging, 0.1 c.cm. of plasma is added to a 3 in. by 1/2 in. test-tube containing 0.1 c.cm. of lung extract* (used as the source of thrombokinase) and 0.1 c.cm. of M/10 calcium chloride solution (to neutralize the oxalate and leave a slight excess for the mechanism of coagulation). A stop-watch is started immediately on the

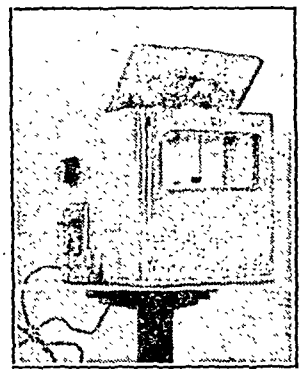

FIG. 1.—The coagulometer.

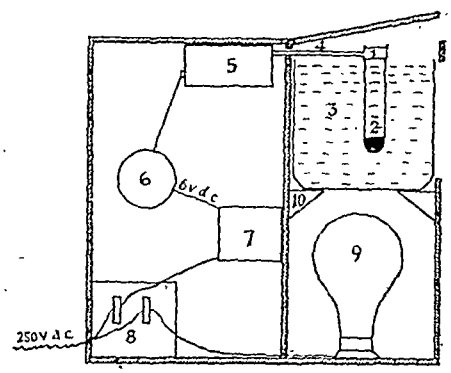

FIG. 2.—Diagram illustrating mechanism of coagulometer. 1: Spring clip. 2: 3 in. by 1/2 in. test-tube. 3: Water-bath. 4: Driving spindle. 5: Motor of "windscreen wiper." 6: Variable resistance for speed control. 7: Transformer and rectifier. 8: Switches. 9: Electric bulb as heat and light source. 10: Bracket to support water-bath. Thermostatic control was found to be *unnecessary*.

addition of plasma, and the tube, after being shaken gently for a few seconds, is transferred to a water-bath at 38° C. It is propelled in the water through an angle of 170 degrees by the apparatus shown in the photograph. This procedure ensures that the temperature and range of movement given to each sample are uniform, besides producing a sharp end-point. The watch is stopped when coagulation occurs. By this method the prothrombin time in healthy persons was found to average 25 seconds and to vary between 24 and 27 seconds. In jaundiced patients it varied between 25 and 140 seconds. Duplicate estimations were carried out, the average difference being 1 second. Because of slight variations in the lung extract, and in order to compare results obtained from day to day in the same patient and in different patients, the "prothrombin index" (Quick *et al.*, 1935) was determined as follows:

$$\text{Prothrombin index} = \frac{\text{Unknown prothrombin time in secs.}}{\text{Normal control prothrombin time in secs.}} \times 100$$

The normal range is 90 to 110. The results are expressed as a percentage of normal..

* Fresh ox-lung extract was used as a source of thrombokinase and was prepared by the method described by Smith *et al.* (1939). This extract lost much of its potency in two to three days if kept at room temperature. This period was extended to three to five days if stored at 9° C., but if immediately placed in the freezing chamber of the refrigerator it retained its activity at least four weeks after preparation. By this time the stock had usually been exhausted. The lung extract, in saline, was stored in fifty small glass tubes of about 1.5 c.cm. capacity, sealed, and immediately frozen. A tube was taken from the refrigerator before it was required to carry out a test.

Personal Observations

This paper describes an investigation of prothrombin deficiency and haemorrhage in obstructive jaundice, biliary fistula, catarrhal jaundice, and cirrhosis of the liver; and the treatment of prothrombin deficiency in some of the patients with a new water-soluble preparation. Finally the possibility of a liver function test based on prothrombin estimations is briefly discussed.

Thirty-five patients have been studied, and repeated determinations of the prothrombin index and quantitative van den Bergh reactions were made in all, and in addition the platelet count (Gram's method modified, Reid, 1940), the bleeding-time (Duke, 1915), the capillary resistance test (Göthlin, 1937), and the coagulation time (recalcifying oxalated blood, Quick *et al.*, 1935) were carried out in three patients with post-operative haemorrhage. In 16 cases definite prothrombin deficiency was found, and these were selected for treatment with synthetic naphthoquinone preparations in order that the efficiency of the drug could be determined. Of these patients 8 received 2-methyl-1:4-naphthoquinone† in peanut oil by intramuscular injection, and 8 were given the new 2-methyl-1:4-naphthohydroquinone disuccinate‡ by intravenous injection. Daily prothrombin estimations were carried out three to five days before and seven to ten days after treatment, and samples of blood were also taken four hours after giving the drug in order to determine how quickly it acted. For convenience of description the patients have been grouped as follows:

1(*a*) Obstructive Jaundice due to Neoplasm

Fifteen patients have been studied—seven males and seven females. The age range of the patients was 29 to 74 years, with the maximum age distribution about the sixty-fifth year. The duration of jaundice before investigations were carried out was two to twenty-two weeks, and the degree of jaundice varied between 11 and 32 mg. of bilirubin per 100 c.cm. plasma.

Before Operation.—The prothrombin index in patients before operation ranged from 31 to 100%, and averaged 65%. Slight prothrombin deficiency was occasionally found when the plasma bilirubin was below 20 mg./100 c.cm., but in most of these patients the prothrombin index was within normal limits. When the amount of bilirubin exceeded 25 mg./100 c.cm. plasma, prothrombin deficiency was always found, and was more pronounced the more the bilirubin in the blood increased above this level—i.e., the more complete the biliary obstruction became and the smaller the quantity of bile entering the intestine. The patients on whom these investigations were carried out were all taking satisfactory diets, including green vegetables, so the dietary intake of fat-soluble vitamin K might be assumed to be adequate. Further, it was found by the American workers and Illingworth that vitamin K concentrates and 2-methyl-1:4-naphthoquinone given by mouth had no effect on the low prothrombin levels in obstructive jaundice and biliary fistula unless bile salts were given by mouth at the same time. Hence the correlation between the degree of prothrombin deficiency and the lack of bile entering the intestine supports the view of the above workers that entry of insufficient bile salts into the intestine, with consequent deficient absorption of vitamin K, is the main cause of the fall in the prothrombin level in obstructive jaundice and biliary fistula.

After Operation.—Marked prothrombin deficiency was encountered in patients after operation, in association with

† 2-methyl-1:4-naphthoquinone supplied by Glaxo Laboratories Ltd. under the trade name kapilon.

‡ 2-methyl-1:4-naphthohydroquinone disuccinate supplied by Roche Products Ltd.

much slighter degrees of obstructive jaundice (e.g., 10 mg. bilirubin per 100 c.cm. plasma). This always occurred, whether it was an exploratory laparotomy or an operation to relieve biliary obstruction. In seven such patients a pronounced prothrombin deficiency developed from the second to the sixth day, the prothrombin index being reduced from 5 to 25% in the first twenty-four hours and from 20 to 50% between the second and the sixth day. (These figures tend to under-estimate the actual results, since treatment was not long delayed after the prothrombin index fell below 50%.) Four possible factors which might account for this considerable post-operative fall require consideration: (1) utilization of prothrombin for coagulation of blood during and immediately after operation; (2) a toxic effect of the anaesthetic on the liver; (3) lack of vitamin K, due to defective absorption from the intestine; (4) deficiency of the vitamin in the post-operative diet.

The first of the above factors was shown to be unimportant, because equally low figures were obtained just before and one to three hours after operation. With regard to the second factor, the seven patients showing the marked post-operative fall responded immediately to treatment with naphthoquinone preparations and the prothrombin index rapidly returned to normal; hence liver damage, while it may be a contributory factor, does not appear to play an important part in producing post-operative deficiency. The third factor—interference with the absorption of vitamin K through the absence of bile salts from the intestine—has just been discussed as a cause of prothrombin deficiency. Four of the seven patients referred to above underwent anastomotic operation for the relief of biliary obstruction. The stools were fairly well coloured before operation, but were even darker on the second and third days afterwards. The maximum fall in the prothrombin index occurred on an average on the fourth day, so that if bile salts were being excreted along with the pigment failure of absorption of vitamin K would not be due to this cause. The fourth factor, deficiency of vitamin K in the post-operative diet—so far as it may be assessed at present—was found to exist, since green vegetables (the only known source rich in the vitamin) were not taken for at least one week.

It would therefore appear that a deficient intake of vitamin K may be important in causing the pronounced post-operative fall in the prothrombin index, but a definite statement on the question must await further investigation.

1(*b*). Non-malignant Obstructive Jaundice

Eight patients, 7 females and 1 male, have been studied. Their ages ranged from 38 to 75 years. Six had chronic cholecystitis with gall-stones, 1 had a post-operative stricture of the common bile duct, and 1 had chronic pancreatitis. All were jaundiced, but not deeply (3 to 7 mg. bilirubin/100 c.cm. plasma), when observations were made.

Before operation the prothrombin index was never below 75%; in 7 it ranged between 80% and 95%. Six patients underwent operation: 4 for removal of gall-stones, 1 for stricture of the common bile duct, and 1 had an exploratory laparotomy. In 4 the prothrombin index ranged between 75% and 80% in the first two days after operation, but thereafter normal values were found. In another patient it fell to 57% on the fourth day, and in the sixth patient it fell to 25% after one week, when haemorrhage from the wound was observed.

Prothrombin deficiency was considered to be due to the causes discussed in dealing with the malignant obstructive jaundice group.

2. Biliary Fistula

There were two patients in this group; their cases are here recorded.

Case 1.—A married woman aged 59 had a cholecystectomy performed for chronic cholecystitis with gall-stones. A complete biliary fistula developed after this operation. Her diet was satisfactory, but the prothrombin index was only 52% after the fistula had been present for ten weeks. On the day following an operation to close the fistula it fell to 36%; 15 mg. of the intravenous preparation was given, and within twenty-four hours the prothrombin index had risen to 88%.

Case 2.—A married woman aged 52 developed a biliary fistula following cholecystectomy for chronic cholecystitis. A repair operation four months after removal of the gall-bladder failed, and a fistula developed, associated with slight obstructive jaundice (immediate direct van den Bergh and 5 mg. bilirubin/100 c.cm. plasma). The stools were light in colour and bile was present in the urine. The prothrombin index was 80% after the condition had been present for eight months, and showed little variation over a period of three weeks. Two days after intramuscular injection of 15 mg. of 2-methyl-1:4-naphthoquinone the prothrombin index was 103%. A second repair operation was successfully undertaken, further treatment having been given the previous day. Despite the fact that the patient was unable to take anything but fluids for the week following operation the prothrombin index never fell below 90%.

No haemorrhage occurred in either of these patients. In the first a biliary fistula prevented sufficient bile salts entering the intestine, with the result that adequate amounts of vitamin K, though present in the diet, were not absorbed, hence the low prothrombin values. The second had a partial fistula and slight obstructive jaundice, but enough bile salts entered the intestine to prevent serious prothrombin deficiency developing. Pre-operative treatment prevented the usual fall in the prothrombin index after operation.

3. Catarrhal Jaundice

Six patients with catarrhal jaundice were subjects of investigation. There were 3 males and 3 females, and the ages ranged from 19 to 30 years. Two suffered from a mild, 3 from a moderate, and 1 from a severe attack of the disease. The prothrombin index was never below 90% and the plasma bilirubin was 5 and 10 mg. per 100 c.cm. respectively in the 2 patients with the mild form of the disease. In the patients with the moderate attack the lowest prothrombin indices were 80%, 72%, and 65%, and the plasma bilirubin was 18, 9, and 7 mg./100 c.cm. respectively. The prothrombin index was 20% and the plasma bilirubin 35 mg./100 c.cm. at the height of the disease in the patient with severe clinical manifestations. He also had extensive subcutaneous haemorrhages and haematomata on the arms, legs, and abdomen, though external haemorrhage did not occur. His diet was good and the rapid improvement in the prothrombin index (20% to 90% in three days) without extraneous vitamin K therapy coincided with the appearance of bile in the stools, though the plasma bilirubin was still 32 mg./100 c.cm.

The prothrombin deficiency in patients with slight jaundice may be due to a toxic effect on the liver, since they were taking a satisfactory diet and bile was known to be entering the intestine. In the patient with marked prothrombin deficiency failure to absorb vitamin K appeared also to be important, since the prothrombin index rose rapidly after the stools were coloured.

4. Cirrhosis of Liver

Investigations were carried out on 4 patients—2 males and 2 females. Their ages ranged from 46 to 65 years. Slight icterus (2 to 4 mg. bilirubin/100 c.cm. plasma) was present in 3, and the stools were well coloured in all 4. The amount of prothrombin in the blood was always moderately reduced, and the prothrombin index ranged from 65% to 80%. On an ordinary mixed diet the level tended to fluctuate between these figures over a period of 3 to 6 weeks. Normal values were never reached, and there was practically no response to parenteral administration of the vitamin K preparation (see Fig. 4).

Post-operative Haemorrhage

Three patients with obstructive jaundice developed post-operative haemorrhage from their wounds. There was no bleeding into the skin or from mucous membranes. A brief clinical outline of their conditions will be given.

Case 3.—A man aged 27 complained of abdominal pain and vomiting after food for ten weeks, and jaundice for two weeks. He was poorly nourished and a mass was palpable in the epigastrium. The stools were light in colour and the urine contained bile. The plasma gave an immediate direct van den Bergh reaction, with 11.5 mg. bilirubin/100 c.cm. On the day before an exploratory laparotomy the prothrombin index was 76%. At operation an inoperable retroperitoneal sarcoma was found, and the wound was carefully closed. Throughout the day after operation he suffered from marked abdominal discomfort and vomiting, resulting in restlessness. In the evening of the same day it was noticed that his dressing was blood-stained and that a general ooze was coming from the wound. After changing the dressing the haemorrhage stopped until the afternoon of the second day, when the prothrombin index was 50%. The platelet count, the bleeding-time, and the capillary resistance test were normal. The coagulation time was slightly prolonged. Ten mg. of 2-methyl-1:4-naphthoquinone was given intramuscularly, and twenty-four hours later, though he was still restless and vomiting, the haemorrhage had stopped and the prothrombin index was 94%. He died on the fourth day after operation. A post-mortem examination was not carried out.

Restlessness, retching, and vomiting, by putting an extra strain on the wound, was probably the main factor in causing the early onset of haemorrhage, and the fact that it was intermittent is probably a reflection on the slight prolongation of the coagulation time.

Case 4.—A man aged 67 complained of jaundice of three days' duration. He was well nourished and took his food well. The stools were brown in colour and the urine contained bile. The plasma gave an immediate direct van den Bergh reaction and contained 8.5 mg. bilirubin/100 c.cm. Before operation the prothrombin index was normal (90 to 96%). A cholecystoduodenostomy was performed for a carcinoma of the head of the pancreas, and twenty-four hours after operation the prothrombin index was 75%. It gradually fell until the fifth day, when it was 55%, and the coagulation time was moderately prolonged. The platelet count, the bleeding-time, and the capillary resistance test were normal. In the evening of this day haemorrhage from the wound was noticed, and later his extremities were cold and he became collapsed. Haemorrhage was more or less continuous for forty-eight hours. The haematocrit reading before the haemorrhage was 40%; afterwards it was 32%, so that probably at least one-fifth of the red cells were lost. The response to treatment is shown in Fig. 3. Satisfactory progress was made until the tenth day; then he became drowsy and dehydrated, and died on the fifteenth day after operation. A post-mortem examination was not performed.

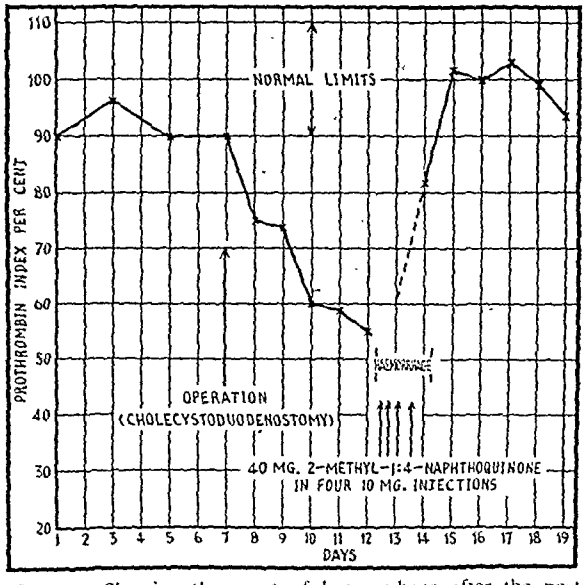

FIG. 3.—Showing the onset of haemorrhage after the post-operative fall in the blood prothrombin and the immediate response to treatment with synthetic vitamin K.

Case 5.—A woman aged 46 complained of intermittent attacks of pain in the right hypochondrium, shivering, and jaundice for the past twelve years. Bile was present in the urine, but the stools were well coloured. The van den Bergh test gave an immediate direct reaction of 6 mg. bilirubin/100 c.cm. plasma. A diagnosis of chronic cholecystitis with obstructive jaundice due to gall-stones was made. A hypochromic anaemia was also present (Hb. 52%; R.B.C., 3,470,000/c.mm.; C.I., 0.73; haematocrit, 30%; W.B.C., 7,200/c.mm.), which was treated successfully with iron. Before operation the prothrombin index was 75%: the platelet count, the bleeding-time, the capillary resistance test, and the coagulation time were normal. A stone was removed from the common bile duct and the gall-bladder was drained. Late in the evening of the sixth day after operation a slow ooze from the wound was first noticed; this continued overnight, and by 10.15 the next morning the patient's extremities were cold and she was collapsed. The prothrombin index was 25% and the coagulation time was much prolonged. The bleeding-time and capillary resistance test were normal. At 10.30 a.m. she was given 15 mg. of 2-methyl-1:4-naphthoquinone intramuscularly, and four hours later the prothrombin index was 75%, the coagulation time was normal, and the haemorrhage had ceased. On the eighth day the prothrombin index was 94%. The subsequent course was uneventful.

Haemorrhage and Prothrombin Deficiency

Haemorrhage associated with prothrombin deficiency has been described in newborn infants, in idiopathic steatorrhoea (Kark *et al.*, 1940), and in hepatic and biliary disease. It may be manifested by ecchymoses, haematomata, and haemorrhage from mucous membranes and even into joints, but it occurs most often from operation wounds (Illingworth, 1939b).

When haemorrhage began in the three cases just described the prothrombin index was 50%, 55%, and 25% respectively. Three patients with obstructive jaundice and one with a biliary fistula showed prothrombin indices of 24%, 26%, 27%, and 36% after operation and yet no haemorrhage occurred. It would therefore appear that there is no constant relation between the degree of prothrombin deficiency and the occurrence of haemorrhage from the operation wound. This statement may be explained by considering that before any serious capillary haemorrhage can occur two conditions must be fulfilled: (1) rupture of the vessels; and (2) an upset in the mechanism for securing haemostasis. Prothrombin deficiency, by interfering with the coagulation of blood (a process of importance in stopping haemorrhage), will thus not necessarily result in haemorrhage, but if rupture of the vessels occurs this interference with the coagulation mechanism will prolong the bleeding. Trauma is suggested as the most frequent cause of rupture of the vessels, since no defect in the capillaries was found, as judged by the capillary resistance test. This is supported by the frequency of haemorrhage from the operation wound, which is a "weak spot" and so more liable to bleed from minor injury.

A Comparison of Haemorrhage in Jaundice and Haemophilia

Four patients with haemophilia were studied. The platelet count, the bleeding-time, the capillary resistance test, and the prothrombin index were normal and the coagulation time was prolonged (4 to 8 times normal).

In the three patients with obstructive jaundice who developed haemorrhage the platelet count, the bleeding-

time, and the capillary fragility test were normal. The prothrombin index was subnormal and the coagulation time was prolonged in proportion to the degree of prothrombin deficiency—e.g., it was four times normal when the prothrombin index was 25%.

It is suggested, from these observations and the clinical manifestations of haemorrhage in the two conditions, that there is a close analogy between haemophilia and haemorrhage in jaundice. A defect in the coagulation of blood exists in both and trauma is the usual determining cause of haemorrhage. The essential difference between the conditions rests in the particular upset in the coagulation mechanism—in the one a prothrombin deficiency and in the other an unknown congenital defect.

Treatment of Prothrombin Deficiency

The object of treatment is to raise the prothrombin index to the normal level of 90% to 110% in order to correct the defect in the coagulation of the blood. The results are shown in the accompanying table. All the

Table showing Effect of Treatment on the Prothrombin Index

Condition	Preparation and Dose		No. of Cases	Prothrombin Index: Before Therapy	Prothrombin Index: 4 Hours after Therapy	Time to Reach Normal (Days)
Obstructive jaundice due to neoplasm	I.M.	10 mg.	6	27–64	}*	3
	I.V.	10 mg.	6	24–53	}	2

patients except those with cirrhosis of the liver responded to treatment (Fig. 4). The marked activity of 2-methyl-1:4-naphthoquinone in increasing the amount of prothrombin in the blood has been confirmed, and it may be concluded that the new intravenous preparation is at least as potent as this drug. The intravenous drug appears to be more rapid in its action than the intramuscular one, but for a prolonged action the latter is probably to be preferred. Definite conclusions on the dosage and the time for the maximum response could not be made, but the results suggest that a more rapid increase in the prothrombin index occurs when the larger doses are given. No toxic effects were encountered with either of these preparations, but two patients complained of pain at the site of intramuscular injection.

In preparing a jaundiced patient for operation prothrombin estimations will decide whether treatment is necessary or not. If these estimations are not carried out during the first week after operation it would seem advisable to administer some active form of vitamin K as a routine in view of the marked fall in the amount of prothrombin which may occur during this dangerous period. For this purpose a depot dose of 15 to 20 mg. of 2-methyl-1:4-naphthoquinone intramuscularly on the day of operation is suggested.

Blood Prothrombin Levels and Liver Efficiency

Suggestions have been made that the amount of prothrombin in the blood may be used to assess liver function, and recently Wilson (1940) has reported a relation between the hippuric acid liver-function test and blood-prothrombin levels. The failure of the patients with cirrhosis of the liver to respond to treatment (see table) may be ascribed to liver inefficiency, since, as previously mentioned, the only known conditions affecting man in which prothrombin deficiency does not respond to vitamin K therapy are associated with severe liver damage. Similar results have been reported by Butt *et al.* (1940) in three patients with cirrhosis.

Laevulose-tolerance tests carried out on three of the four patients in whom the above investigations suggested liver inefficiency were normal. Later two of these patients died, and post-mortem examination revealed advanced cirrhotic changes. Thus it may be that the failure of naphthoquinone preparations to increase the subnormal amounts of prothrombin in the blood in patients suffering from chronic hepatic disease such as cirrhosis may prove to be a valuable index of liver inefficiency. This matter is being investigated, and it is intended to make it the basis of a subsequent communication.

Summary

The importance of vitamin K in the prevention and treatment of haemorrhage in hepatic and biliary diseases associated with jaundice has now been fully recognized. The present investigations support previous work indicating that defective absorption of vitamin K due to absence of bile salts in the intestine is chiefly responsible for prothrombin deficiency in obstructive jaundice and biliary fistula prior to operation.

It is suggested that prothrombin deficiency after operation in these conditions—a deficiency which is often pronounced—may be due to a deficient intake of vitamin K in the restricted post-operative diet. Routine pre-operative administration of vitamin K is recommended.

The prothrombin deficiency in cirrhosis of the liver is considered to result from imperfect utilization of vitamin K by the liver.

Prothrombin deficiency is not, even when severe, always associated with haemorrhage. It is considered to be responsible only for the prolongation of haemorrhage after it has been caused by other factors, especially injury.

A new water-soluble preparation (2-methyl-1:4-naphthohydroquinone disuccinate), injected intravenously, has been found

to be as efficient as 2-methyl-1:4-naphthoquinone in increasing the amount of prothrombin in the blood when there is a deficiency. Moreover, the action of this preparation appears to be more rapid though less sustained than the latter. It has one minor disadvantage in that it is not stable for long in aqueous solution, and so has to be dissolved in water immediately before use.

A close analogy between haemorrhage in jaundice and haemophilia has been made. In both an upset in the coagulation mechanism exists, which is due in the one to prothrombin deficiency and in the other to an unknown congenital defect.

The failure of the patients with cirrhosis of the liver to respond to naphthoquinone preparations suggests that prothrombin estimations may form the basis of an additional test of hepatic insufficiency. This possibility is being explored.

A simple apparatus for determining the coagulation time and prothrombin time has been illustrated and a method of preserving lung extract, used as a source of thrombokinase, has been described.

I wish to thank Profs. J. W. McNee and C. F. W. Illingworth for advice and criticism, the physicians and surgeons of the Western Infirmary for permission to examine and treat the patients under their care, and Glaxo Laboratories Ltd. and Roche Products Ltd. for supplies of vitamin K.

The committee of the Royal Melbourne Hospital has accepted responsibility for the erection of a new building for the Walter and Eliza Institute of Research in Pathology and Medicine, now in its twenty-first year. The building will provide additional laboratory space and greatly improved facilities. Meanwhile the annual report of the Institute chronicles a large amount of work, some of it routine investigation and some of it called for by the special demands of the war, in the virus department, the biochemical department, and the departments of clinical and neuropathological research. Much of the work has already been published in Australian journals. Last year the Institute started a blood bank, the only one so far established in Melbourne, to meet emergency blood transfusion requirements. A considerable part of the Institute's work has been the determination of the blood groups of nearly 13,000 troops of the A.I.F. in camp in Victoria. Research has also been undertaken on changes observed during storage of blood, and on the treatment of anuria following incompatible blood transfusions. Endeavours have been made to find a solution which, when injected intravenously in small amounts, will cause rapid alkalinization of the urine. A dose of 20 c.cm. molar sodium lactate solution shifts the *p*H of urine to the alkaline side and maintains it there for half an hour, and it is thought that it may be possible to produce more significant effects with larger doses or more concentrated solutions.

EXPERIENCES IN THE RECEPTION AND TREATMENT OF AIR-RAID CASUALTIES

BY

JOHN ROBERT LEE, M.D., B.S., F.R.C.S.

These notes cover a period of two months when intensive enemy air raids occurred over London. During this period 227 patients came under my care and supervision. Many of us have seen and treated badly injured civilians brought to hospital as the result of road, railway, or works accidents in peacetime. It seems to me, however, that only those who have had to deal with victims of air raids can conceive the appalling condition and appearance of many of these patients on their arrival in hospital. A sight which must be seen to be appreciated fully is the almost indescribably filthy condition of many who evidently had been clean and well clad. A patient is brought to the receiving ward with her clothes cut and torn to shreds, her hair singed, filled with dirt, and matted with blood and cement dust, her body and limbs covered with grit and oil, her face blackened, bruised, and bleeding, her eyes, nose, lips, and ears filled with dirt, her head bandaged, and her limbs immobilized by improvised splints at the first-aid post. Truly it is a picture not easy to forget. Most badly injured patients had been given 1/4 grain to 1/2 grain of morphine; the latter seemed too big a dose. Their ages varied from an infant a few hours old, born and bombed on the same day, to a man aged 92. There were twelve children under 14 years and twenty-six patients over 70. Thirty-six patients were dead or moribund on arrival in the receiving-room. The other patients were classified as follows:

Group 1 consisted of those so terribly injured that they died within an hour of arrival.

Group 2 patients were a few so badly hurt and shocked that they died notwithstanding most prompt measures taken for their resuscitation. Two of these were in so much pain that morphine and other usual sedatives failed to relieve. The administration of repeated short inhalations of chloroform was found to be the only way to calm these patients and to relieve their agony.

Group 3 was made up of those suffering from severe shock and loss of blood. These responded to blood transfusion, other resuscitation measures, and good nursing. After some hours—up to twenty-four—they were in a fit condition to be operated on, and made a good recovery. Some in this group had shattered limbs or had lost part of a limb. Others had head injuries with open or closed fracture of the skull. Three had protrusion of brain substance. All three recovered. Four patients had fractured spine. Two had penetrating abdominal wounds. Others suffered from severe burns.

Group 4 included patients less severely injured. They had large lacerated wounds or open or closed fractures, but shock was not so marked.

Group 5 comprised patients suffering with multiple small cuts, abrasions, and bruises.

Our Routine

Faced for the first time with conditions as described, we evolved and adopted the following routine plan. The patient was at once assured he would be safe and well cared for; those who were distressed because they could not see owing to dirt, swelling, or eye injury were told not to fear going blind. Their eyes were thoroughly cleansed and castor-oil instilled at once, and their lips and mouths were also cleaned. The patients then had a

cup of fresh tea with sugar. Antitetanic serum was given to all the wounded. Brief notes were written and any such treatment was recorded on the case sheet, especially if morphine had been administered at the first-aid post. The patient was then sent to the ward. The nursing staff carried out their duties efficiently, often working on far into the night after a long day. Patients well enough were removed from the stretchers and put to bed. Several of those in one of the first three groups were too ill to be moved off the stretchers for some hours. As soon as such a patient arrived in the ward all special measures for resuscitation were begun, and carried out, by the hospital staff and by special teams, whose skill and untiring efforts saved many lives and enabled us to operate and to obtain good results.

Three patients who were very ill and had been given several pints of blood responded very well indeed, then after a few hours they suddenly showed pronounced signs of apparent collapse, with profuse cold clammy sweat, dilated pupils, rapid very feeble pulse, and restlessness. A hypodermic injection was given consisting of morphine grain 1/4, strychnine grain 1/60, and atropine grain 1/100—the tablet known as M.S.A.—with a good result in each case.

All wounded patients were given the full prescribed course of sulphapyridine with the usual routine hygienic and dietetic measures, combined with good nursing. We soon evolved the following method in cases of injuries to the head or limbs with extensive lacerated wounds.

Patients when well enough to be operated on were given preliminary medication, including 1/100 grain of atropine, and taken to the theatre still on the stretchers on which they were admitted. A general or more often an intravenous anaesthetic was administered: then what we termed a "cleansing squad," which included a doctor, sister, nurse, and one or two attendants, removed the patient's clothes, and thoroughly cleansed the injured parts with ether soap and hot water over a large flat dish and mackintosh. In wounds of the head the hair was cut away. The area adjacent to the wound on the scalp or a limb was shaved, washed with a solution of dettol, and placed in a suitable position on sterile towels. The surgeons were then able to operate with reasonable aseptic and antiseptic care. The area adjacent to the wound was painted with dilute tincture of iodine. Wounds were carefully examined and explored, and foreign bodies and debris were removed. Skin edges and other damaged tissues, especially devitalized muscle, were excised. In a few cases sulphanilamide powder was freely placed in the wound, which was then closed by sutures somewhat widely placed and without tension. Rubber tubing or other material was not used for drainage. Suitable dressings were applied and, if necessary, as in a bad wound of a limb, local rest was obtained by the use of a splint for a few days. We found it a good plan in some cases when a patient had multiple wounds, say of head and a limb or two limbs, for two surgeons to operate on the patient, each doing one part, and so lessening the time the patient was under the anaesthetic. The results were gratifying.

Use of Glycerin and Iodine

From experience gained from dealing with those injured in railway and road accidents during recent years, I treated nearly all wounds by using glycerin and iodine instead of sulphanilamide. Our records show uniformly good results. We proved the value of the method in this series. It must be obvious that many wounds cannot be thoroughly excised. Three cases serve to illustrate this point very well.

A young man had a three-inch curved wound along the lower margin of his left orbit which extended deeply into the antrum. The skin was excised, and debris and small foreign bodies and fragments of loose bone were curetted out by using gauze on an artery forceps. The cavity was filled with glycerin and iodine and the wound was closed with a subcuticular suture. After suture the wound was painted freely with the solution. No dressings were applied. The wound healed without any complication. The patient was transferred to a base hospital, and returned to us for discharge within fourteen days of the injury.

Another case was that of a middle-aged woman who had a four-inch oblique wound which extended from near her right external orbital process, with a fracture of the upper jaw, through the zygoma into the pterygoid fossa. Exactly similar treatment was given with an equally good result.

A third patient, a girl aged 15, apparently had a large glass tumbler blown through her left shoulder. Nearly all of the body of the scapula, its neck, glenoid cavity, acromion, and coracoid, the outer third of the left clavicle, and the head and upper three inches of the left humerus were blown away. Her left upper limb was attached to her body by its vessels, nerves, and a band of skin about two inches wide. Her condition was desperate. The huge wounds in front of and behind what was her shoulder were filled freely with glycerin and iodine while resuscitation measures were being carried out. After thirty-six hours she was taken to the theatre and attended to as described herein. Portions of her coat and other clothes, with dirt and debris, were removed from the wounds, then more glycerin-and-iodine solution was constantly applied. Gas gangrene was feared, as cultures showed the presence of *B. welchii*. A dose of anti-gas-gangrene serum was given. She did not develop gas-gangrene. At the end of five weeks she was able to move her elbow, forearm, wrist, thumb, and fingers well. The wounds were almost healed, and her general condition was good.

Many patients had literally scores of wounds on the face, body, hands, and legs. Excision was out of the question. These were treated by having the wounds curetted with gauze soaked in glycerin and iodine. On the face no dressings were used. The wounds were frequently painted. The small scabs were shed in about a week. Multiple wounds of the limbs were painted, and a sterile towel was placed so as to prevent contact with the bedclothes. All such wounds healed in less than a fortnight with very little scarring. By this method healing takes place rapidly under a scab with little or no pus, usually in less than a fortnight. There are no repeated painful dressings. The growing tissues are not damaged. The circulation and local nervous mechanism are not interfered with by bandages or other material placed around a limb. Every effort was made to avoid amputation, usually with satisfactory result.

Treatment of Burns

Before the more recent instructions were issued concerning the treatment of burns with tannic acid, two patients, a man and his wife, had severe burns of the face, forearms, and hands. Tannic acid had been applied. We noticed the hard claw-like fingers beginning to develop. The patients complained of much pain in the finger-tips. Hence I treated the cases with zinc oxide cream, which was very freely applied. The patients said the pain ceased after two hours. The black eschars softened and then peeled off, and both patients made an uninterrupted recovery, now having full use of their hands.

Conclusion

On three occasions when we had many severe casualties a mobile team was sent to help us. We found that, while their help was valuable, the disadvantages were that they did not know the run of the hospital, and that the theatre staffs had not worked with them: hence there were difficulties and delays. We were badly bombed on three occasions, and so our telephone service was cut off just when we needed it most. From this cause difficulties of arranging transport and transfers to base hospitals arose. We found it best to keep Group 3 patients under our own

care and treatment. None of these developed gas gangrene or serious sepsis.

The courage and cheerfulness of the patients were most remarkable. For example, one woman about 52 years of age, when asked how she was, said: "Oh, I've only a few cuts and scratches"; and added, "Hitler can't get me; he bombed me once before and blew the roof off my house. I was downstairs this time. My house is now down flat, and I won't be there next time he bombs it." Visitors were allowed freely, but were warned that there were to be "no tears" while in the wards.

I wish to express my thanks to the medical superintendent and his staff, and to the nursing staff, stretcher-bearers, and scouts, for their constant help and real team spirit in great emergencies.

RENAL COMPLICATIONS OF SULPHAPYRIDINE

ACCOUNT OF A CASE WHICH SHOWED GROSS HAEMATURIA AND URAEMIA

BY

J. C. LEEDHAM-GREEN, F.R.C.S.

Honorary Assistant Surgeon, North Staffordshire Royal Infirmary; Temporary Major, R.A.M.C.

Although haematuria is generally recognized as an occasional complication of sulphapyridine treatment it is a condition which has received little attention in the literature of this country. All the information that I have been able to glean has been culled from communications published in the United States and in Canada, and from a summary of part of this transatlantic work by R. St. A. Heathcote (1940). The object of this paper is to report a case in which haematuria and uraemia occurred, and to give a general description of the renal complications of sulphapyridine (Backhouse, 1939).

Case Report

A second lieutenant aged 26 was admitted to hospital on August 26, 1940, with follicular tonsillitis. He gave a recent history of three similar attacks. There was no elevation of pulse or temperature. He was put on to sulphapyridine and given gargles of potassium chlorate. The following day he felt better and his throat was less painful. On August 28 he vomited several times and passed 10 oz. of deeply blood-stained urine. The sulphapyridine, of which he had received a total dose of 12 grammes, was stopped. He passed 1 oz. of urine during that night, and in the early morning of the 29th had a severe attack of pain in the lower abdomen, which radiated later to the penis. During the day he passed only 5 oz. of urine, which was grossly blood-stained. He continued to vomit throughout the day, and still complained of pain in the abdomen and across the lumbar region. In the evening he was very drowsy.

On August 31 an intravenous "drip" saline was started, as he was vomiting intermittently and had passed no urine for forty-eight hours. At this time his tongue was dry and furred, and occasional hiccups had begun to add to his distress. He was tender in the left iliac fossa and left costo-vertebral angle, and slightly tender in the right iliac fossa. There was no evidence of oedema. A blood count showed Hb 90%; R.B.C. 5,500,000; W.B.C. 11,250—78% polymorphs, 15% lymphocytes, 7% monocytes. During the night he became restless and delirious. The "drip" was stopped on the morning of September 1, by which time he had received 4 pints of normal saline and 2 pints of 5% glucose in normal saline. At the end of the drip his mental outlook was rational and his tongue had become moist. He was still vomiting, but less copiously and less often, and had not yet passed urine. During the afternoon another intravenous "drip" was started, 1 pint of normal saline being followed by 2 pints of 5% glucose-saline, and the same evening he passed about 1/2 oz. of bloody urine after a period of anuria lasting seventy-two hours. The specimen of urine was examined by Major C. E. van Rooyen, who reported as follows: "Specimen consists of about 1/2 oz. of blood-stained urine—cloudy, dark, and with much amorphous granular sediment. Microscopical examination: Numerous R.B.C. and pus cells; no bacteria; no crystals of any sort visible." This urine was passed at 8.30 p.m. At 9 p.m. a solution of 4.28% sodium sulphate was substituted for the glucose-saline, and at 9.45 p.m. a further 6 oz. of urine was passed. By the following morning the patient had passed 82 oz. of urine. The "drip" was continued till the morning of September 3, by which time 8 pints of saline and glucose and 2 pints of sodium sulphate solution had been given. From now on his condition rapidly improved and gave rise to no further anxiety. On September 11 a centrifuged deposit of urine showed W.B.C. (average 20 per field), R.B.C. (average 6 per field), 4 epithelial casts, and 1 hyaline cast.

On September 17 an excretory pyelogram revealed no abnormality of outline or function. Tonsillectomy was performed by Major E. A. M. Connal on September 23, and the patient was discharged from hospital on October 4.

Incidence of Renal Complications

Plummer and Ensworth (1939) reported 4 cases of gross haematuria and 1 of microscopical haematuria in 323 patients treated with sulphapyridine. They also observed a mild degree of blood nitrogen retention in 3 patients who showed no haematuria. These authors maintain that in their experience of the toxic effects of sulphapyridine "those involving the kidneys and ureters have been the most disturbing." Duncan Graham of Toronto and his co-workers (1939) observed 4 cases of gross haematuria in 50 patients, Smith and Needles (1939) 1 case among 50; while Tsao, McCracken, Chen, Kuo, and Dale (1939) have reported 5 cases of gross haematuria in a series of 40 patients, but attribute this high incidence to the poor nutrition, dehydration, and avitaminosis which were features of most of their patients. Tsao's patients were children attending a hospital which admits only sick refugee Chinese. In the case of almost all the patients in these various series pneumonia had been the primary disease for which the sulphapyridine was given. My colleague Captain J. A. Scott (personal communication) has noted a case of gross haematuria among 74 patients treated with sulphapyridine for gonorrhoea.

We know from the work of Antopol and Robinson (1939) and of Gross, Cooper, and Lewis (1939) that urinary calculi composed of acetyl-sulphapyridine (64.1%) and sulphapyridine (6.4%) can be produced experimentally in monkeys, rabbits, and rats by the oral administration of large amounts of the drug; and two small stones of acetyl-sulphapyridine were found by Plummer and Ensworth at necropsy in the kidney of a woman who over a period of three months had received 540 grammes of sulphapyridine on account of a subacute bacterial endocarditis. It is important to bear in mind, however, that massive doses of the drug are not essential to effect its precipitation in the urinary tract. Plummer and McLellan (1940) found the crystals in the bladder of a man aged 46 who developed pain in the left flank and haematuria after 11 grammes, and in the case described above only 12 grammes had been given. Nor does this precipitation depend upon a high level of the blood sulphapyridine. In fact, in Plummer and McLellan's case the level was too low to be read.

Nature of the Renal Lesion

In their experimental animals Antopol and Robinson found changes ranging from a simple calculous pyelitis and ureteritis to a marked pyelonephritis. Tsao has reported the post-mortem appearances in a boy aged 5 who had died of uraemia after receiving 7.78 grammes of

sulphapyridine. The pelves and ureters were dilated and their mucosae thickened, congested, and haemorrhagic; the bladder contained a small amount of grey sandy particles, and both ureters were blocked by concretions at their entrance into the bladder. Unfortunately the sand-like material was lost in the fluids and could not therefore be examined for sulphapyridine. Stryker (1940) had the opportunity of examining at necropsy the renal lesion in a child of 5 months who had died of pneumococcal meningitis and had developed gross haematuria after 44.2 grammes of sulphapyridine, administered over a period of four weeks. In this case the mucosa of the urinary tract appeared normal. In the calices and pelves of both kidneys a small amount of yellowish-white gravel was found, and four calculi were isolated from the pelvis of the right kidney. Here, as in Tsao's case, there was an accumulation of gravel in both ureters, mostly at the entrance of the ureters into the bladder. Microscopically the kidneys showed dilatation of the cortical tubules and glomerular spaces due to precipitation within the tubules of concretions of varying structure—namely, sharp-edged basophilic crystals, amorphous basophilic debris, and discoid bodies of homogeneous material.

Diagnosis

When haematuria is observed in a patient to whom sulphapyridine is being administered it must always be borne in mind that the drug may be responsible, and the urine should be examined for crystals. The crystals are elongated and sharp, and occur in clusters grouped at one end and radiating at the other. They are well shown in a photograph reproduced in Plummer and McLellan's paper. It is worth noting that in Captain Scott's case the crystals could not be identified in the centrifuged deposit of the urine, but they could be seen clinging in abundance to the sides of the glass vessel and showed the typical structure under the microscope. The crystals were washed off the sides of the vessel, tested chemically, and identified as sulphapyridine by Miss Gilchrist of the biochemical department of the Royal Infirmary, Edinburgh. Unless concretions of acetyl-sulphapyridine are present in large quantities they are readily redissolved and cannot be identified in the urine. Southworth and Cooke (1939), for example, found them in the urine of only 1 of 3 patients who developed haematuria after sulphapyridine. Occasionally renal calculi of acetyl-sulphapyridine may be demonstrated as negative shadows in excretory or instrumental pyelograms (Plummer and McLellan, 1940). In spite of the sulphur-containing radical the stones themselves are not opaque to *x* rays. In the absence of crystals it may be difficult, and at times even impossible, to determine at the onset whether the haematuria should be attributed to the sulphapyridine or whether it is a symptom of an acute nephritis, since many of the patients under treatment with the drug are victims of acute infections in which nephritis is known to occur as a complication. If the bleeding is due to acute nephritis numerous casts in the urine or oedema or shivering attacks will eventually point the diagnosis. These symptoms are no more characteristic of renal damage due to sulphapyridine than they are of aseptic calculous pyelitis and ureteritis in general. Furthermore, the haematuria due to sulphapyridine is often accompanied by renal pain or colic which is far more severe than the lumbar pain that is an occasional feature of acute nephritis.

Occasionally pain precedes the appearance of haematuria, and Southworth and Cooke (1939) describe a case in which the possibility of an acute appendicitis was seriously debated. The patient was a girl of 17 who developed a transient attack of pain in the right lower quadrant of the abdomen two days after she had been started on a course of sulphapyridine for a respiratory condition. On the following day the pain recurred and was accompanied by burning pain on micturition. Tenderness was most marked over McBurney's point. Owing to the onset of gross haematuria and the fact that her abdominal tenderness extended up to the right costo-vertebral angle, conservative treatment was decided on, and the sulphapyridine, of which she had received 10.5 grammes, was stopped. Her symptoms subsided rapidly.

Treatment

As a rule the symptoms of haematuria and renal colic disappear within twenty-four hours when sulphapyridine is withheld and fluids are forced. In the event of signs of nitrogen retention 5% glucose or 4.28% sodium sulphate solution should be administered by the intravenous "drip" method. If anuria develops and persists in spite of these measures, cystoscopy and ureteric catheterization or, if need be, renal pyelotomy, as suggested by Tsao, deserve consideration owing to the tendency for plugs of concretion to block the orifices of the bladder. This was not carried out in the case I have described, as it was not until the patient had recovered that I had the opportunity of perusing the relevant literature and of learning something of the nature of the condition.

I wish to acknowledge my thanks to Colonel J. M. Mackinnon for permission to publish this record, and to Major C. E. van Rooyen for his friendly co-operation. My grateful thanks are also due to Major Ian Murray for much helpful discussion during its preparation.

EXPERIENCES IN TREATMENT OF PERIPHERAL NERVE INJURIES WITH AMNIOPLASTIN

BY

LAMBERT ROGERS, F.R.C.S., F.R.A.C.S., F.A.C.S.

Surgeon Captain, R.N.V.R.; Consultant in Neurosurgery to the Royal Navy; Professor of Surgery, University of Wales

For some time efforts have been directed towards finding a substance which would isolate a damaged structure by preventing it adhering to its surroundings and which by ultimately becoming absorbed would leave the structure concerned quite free. Wilder Penfield and his associates (Chao *et al.*, 1940) experimented on cats by placing various membranous materials between the scarified cerebral cortex and a flap of overlying soft parts. They found that of the materials used the best was a prepared form of human amniotic membrane which they called amnioplastin. This was absorbed in about three weeks, leaving the cortex free from adhesion.

Following Penfield's report it appeared that this substance would be useful in the surgery of peripheral nerves as well as in that of the central nervous system. Having had some experience of it in eight intracranial cases in which it was used to prevent meningo-cerebral adhesions, and having noted the frequency with which peripheral

nerve lesions so far met with in the present war are due to the involvement of nerve trunks in scar tissue, I thought it desirable, after freeing such trunks, to attempt to isolate them by wrappings of amnioplastin. It is not proposed here to discuss the intracranial uses, but, in order to afford comparison with peripheral lesions similarly treated, an example is given of the type of cerebral case in which the membrane has been used.

Type of Cerebral Case

Old Gun-shot Wound of Head. Meningo-cerebral Adhesions: Traumatic Epilepsy

A fitter aged 51 had three years previously been shot through both frontal lobes with a large-calibre revolver bullet. Dense meningo-cortical adhesions anchored both frontal lobes and were regarded as responsible for his epileptic fits, which had developed subsequently to the shooting accident. On May 7, 1940, a large bone flap was turned down; the adhesions were separated by endothermy, and the frontal lobes were wrapped in amnioplastin. He has remained well and free from fits since.

Peripheral Nerve Cases

The membrane has been used in 12 cases of injury involving the following peripheral nerves: ulnar 2, median 4, musculo-spiral 1, great sciatic 2, external popliteal 3. Brief details of these cases are shown in the accompanying table. It is realized that these are early days in which to draw conclusions as to ultimate results, and I have not yet had an opportunity to reopen a wound and re-examine a nerve trunk that has been isolated by the membrane some time previously; but the results up to date are so encouraging in the incomplete lesions and cases of causalgia so far dealt with that it appears advisable to report our experiences.

Preparation, Preservation, and Method of Using Amnioplastin.—The amnioplastin has been prepared in the surgical unit at Cardiff by Mr. Charles Langmaid and members of the unit laboratory staff from placentas obtained from the obstetric department, in charge of Prof. Gilbert Strachan. The method of preparation has been that described by Penfield and his associates (Chao *et al.*, 1940; Penfield, 1940), and the membranes have been preserved in alcohol (70%), in stoppered bottles. Just before use—i.e., on the morning of operation—enough amnioplastin for what is intended is removed from its storage in spirit and boiled for half an hour in distilled water in a large beaker. After boiling, the amnioplastin, which is slightly cloudy when it comes out of spirit, is more transparent and is of a light green colour. It is not unduly fragile, is easily handled, and resembles rather thin oil-silk. It is taken from the beaker and floated on saline in a large bowl, when pieces may be cut to the requisite size and shape.

Technique of Use in Peripheral Nerve Cases.—The nerve trunk having been isolated and freed from scar tissue both above and below the level of the lesion, and bleeding having been attended to meticulously, so as to obtain a dry field, the site of the lesion (which may be a suture line, an area that has been strangled by dense fibrotic tissue, or a length of nerve anchored by numerous adhesions) is wrapped around by a suitably shaped piece of amnioplastin. This piece must be large enough to extend beyond the limits of the lesion in order to include some normal nerve trunk both above and below it and thus completely isolate it.

Results

Except in one intracranial case, that of a large recurrent meningioma, all wounds have healed by first intention. Results have been both gratifying and encouraging. Early functional restoration has been noted in most and a freedom from pain in all. The relief of pain, cessation of sweating, and early restoration of normal skin appearances in the two examples of causalgia have been particularly striking. It remains for the future to determine whether the late results of these peripheral cases are equally good, and for an opportunity to occur by which we may ascertain from the condition of the operation field whether neural isolation persists and whether the membrane is absorbed as completely in man as in experimental animals.

Table giving Details of Peripheral Nerve Lesions treated by Amnioplastin Isolation

Case	Age	Lesion	Operation	Date of Operation	Result
1	22	Ulnar. Bomb wound, forearm, Aug., 1940. Motor paralysis absolute; sensation lost over ulnar distribution	Freeing of nerve from dense adhesions. Wrapped in amnioplastin	20/11/40	Almost complete recovery within six weeks
2	20	External popliteal. Bomb wound, May, 1940. Drop-foot	Freeing of nerve from scar tissue. Wrapped in amnioplastin	26/11/40	Progressive recovery—not yet complete
3	27	Median at wrist. Causalgia. Cut tendons and nerve. June, 1940	Freeing of nerve from scar tissue; incision made into nerve. Wrapped in amnioplastin	26/11/40	Pain relieved, sweating ceased. Rapid recovery—incomplete
4	19	Median in arm. Musculo-spiral at elbow. Bomb wound at Dunkirk, May, 1940	Freeing of median nerve, which has been partially divided, from dense scar tissue	29/11/40	Slight improvement
5	26	Median just below elbow, following crush of arm in watertight door and fracture of ulnar, Sept., 1940	Nerve found to be embedded in extremely dense scar tissue. Nerve freed and wrapped in amnioplastin	20/12/40	Much recovery in short time
6	20	Median at wrist. Bomb wound of forearm, May, 1940. Causalgia	Neuroma involving median and tendon of flexor carpi radialis. Neuroma dissected off nerve., Incisions into trunk of nerve	2/1/41	Pain relieved. Recovering
7	23	Great sciatic in buttock and comminuted fracture of great trochanter by machine-gun bullet, Aug., 1940	Nerve exposed and found to be partly destroyed at its exit from pelvis; much scar tissue around it. Freed; isolated in amnioplastin	31/1/41	No change
8	28	External popliteal and fracture of fibular neck, Nov., 1940	Exposure of nerve and isolation in amnioplastin	17/2/41	Recovering rapidly
9	21	Musculo-spiral. Wrist-drop following inoculation with T.A.B., Oct., 1940	Exposure of nerve; separation of adhesions; isolation in amnioplastin	25/2/41	Recovering
10	20	Great sciatic in buttock. Injury by injection into nerve, June, 1940	Perineuritis. Isolation in amnioplastin	7/3/41	Recovering
11	19	External popliteal lesion and fracture of fibula by bomb explosion, Jan., 1941	Nerve found divided; proximal neuroma. Neuroma excised; end-to-end suture with knee flexed; amnioplastin isolation	27/3/41	No change as yet
12	35	Fractured surgical neck of humerus; damaged median and ulnar trunks. Accident at sea, Dec., 1940	Perineuritis and myositis ossificans. Isolation of nerve trunks with amnioplastin	29/3/41	No change as yet

Conclusion and Summary

Amnioplastin appears to be a valuable material for the isolation of nervous elements. Its use so far in the surgery of peripheral nerves has been encouraging, relief of pain and restoration of early function being noted in cases in which it has been used after freeing nerves strangled in scar tissue.

Experience in the use of amnioplastin has been obtained in 8 intracranial cases, 12 peripheral nerve cases, and in one or two additional instances, such as a scar in the popliteal space. The type of peripheral nerve case in which the membrane has been used, the method of its employment, and the results so far obtained are here reported. These results are so encouraging as to suggest its continued and further use.

A HISTORY OF THE RESCUE AND AFTER-CARE OF TWO CASES AFTER FOUR DAYS' BURIAL

BY

G. S. SWAN, M.B., Ch.B.

On a Thursday, at 1 a.m., a bomb struck a block of three-storied cellared houses. Some of these houses were completely destroyed. As it was known that a number of people were in them at the time of the disaster rescue work started almost at once, but with little hope of saving anyone alive. At 6 p.m. on Friday an elderly woman was rescued alive, but in such a serious condition that she died a few days later.

The First Rescue

At 7 p.m. on Sunday I was sent for, as the rescue squad had heard a voice under the debris. On arrival I made contact with the trapped girl, one of my own patients, Miss F. B., aged 21, whose voice could faintly be heard, obviously at some distance below the debris. She told me her name, that she knew her father and mother were dead, and that she was quite immobile except for a little movement of the left hand. It was astonishing to find her so completely intelligent, and throughout the six hours before she was finally removed at 1 a.m. on Monday—exactly ninety-six hours from the time she was first trapped—she retained her intelligence and was of great help in guiding the rescue squad in their difficult task.

At 9.30 p.m., debris having been removed entirely by hand and several wooden beams sawn through, a narrow hole four feet in depth allowed of contact with the girl's left hand. It was just possible to feel her pulse, which was well perceptible at about 90 beats per minute. A short time afterwards her head was uncovered, when it became obvious she was face downwards in position. By means of a length of rubber tubing and a feeding-cup we succeeded in getting her to rinse out her mouth, after which she was allowed to swallow a little hot well-sugared tea. Shortly afterwards, as more of her body became exposed, I gave her one-third of a grain of morphine, and about quarter-hourly sips of tea, by now out of the feeding-cup direct. By midnight she was completely exposed at the bottom of a deepish hole. The rescue squad also succeeded in burrowing sideways at her body level, a burrow sufficient to admit head and shoulders with debris supported by some flooring cross-beams. It was through this burrow that we succeeded in delivering her.

She was lying crouched, face down, her knees on her chest and heels under her buttocks, her right arm under her chest and left arm by the side of her face—a normal breech position. Across her back was the dead body of her father. It was evident we dared not remove him before the girl, so we arranged the rescue squad with one man from above easing up the dead body as much as possible, another down the main hole supporting the chin, and a third grasping her hips and gently pulling her through the small narrow side burrow. As she was being removed she told us there was a woman alive next door. Once on the warm stretcher I immediately straightened her legs and sent her to hospital, where all was in readiness for her reception.

The Second Rescue

On investigating her report that a woman was alive next door, we found, to our surprise, that this was true. After shouting we heard a voice say, "I am A. D. [aged 34]; I am all right, and walking about in the cellar. I have a baby with me, who is not very well, and we have some bottles of milk." This turned out to be delirium, and it was some hours before contact was made. It was then discovered that she was lying on the cellar stairs, her head higher than her feet, and completely immobile.

The only way to deliver her was through a narrow aperture formed by the absence of the upper panel of a door, the rest of the door supporting a mass of debris. It was impossible to risk cutting away the side of the door, but it was possible to remove a triangular piece of the lower panel. Her pulse was weaker than the girl's, but countable at about 100. She also received morphine, and was fed in a similar way to the first patient. The dead body of a 3½-year-old boy was lying under her right arm. To deliver her through this narrow aperture one man was able to step inside the hole and just scramble down to place both hands under her shoulders; another man, lying on the debris held by his heels, was just able to reach her legs. I lay over the aperture and, as she was eased upwards, succeeded in grasping her shoulders and bringing her out of the hole over my own right shoulder to stretcher-bearers behind. This was at 6 a.m. on the Monday, 101 hours after being buried. She also was immediately sent to hospital.

Treatment of the Patients

When admitted both patients were placed in warm beds with suspended cradle lamps and received a transfusion of two pints of plasma. Blood pressure on admission was: Miss F. B., systolic 85, diastolic ?; Miss A. D., systolic 90, diastolic ? 70. After transfusion both blood pressures were 140/80.

General Examination of Case I.—Severely shocked, but perfectly conscious and mentally very alert. Very thirsty. Eyes bright and free from grit; lips and tongue abrased and some dirt ingrained; air passages clear—no evidence of gritty lungs. A few small pressure sores on back and large area over sacrum. Full range of movement in upper limbs; small superficial patches of skin gangrene over patellae; both lower limbs stiff, and foot-drop present on left. One gramme of sulphanilamide four-hourly for forty-eight hours, followed by one tablet (0.5 gramme) four-hourly for four days. Frequent hot drinks taken very well. All pressure sores dressed with gentian violet; nursed on an air-bed; right foot splinted; rest of skin perfectly clear. Extremities were warm.

General Examination of Case II.—Severe shock; cold; mental condition incoherent with periods of delirium; very thirsty. Eyes clear; tongue dry; air passages clear—no evidence of gritty lungs. Bruising of both legs, with large gangrenous patch on right thigh posteriorly, lateral aspect of right leg, and above left outer malleolus; a smaller patch of superficial skin gangrene on right side of chest, also on both wrists posteriorly. Patient was not able to move either of lower limbs; the right leg and foot were oedematous, also right hand and arm. Warm fluids were

taken freely. All patches were treated with gentian violet, and sulphanilamide was given as in previous case.

Both patients also received 2,000 units A.T.S. Within twenty-four hours mental condition became perfectly clear; right foot-drop developed, and foot was accordingly splinted.

Subsequent History

Both patients steadily improved. No vomiting; solid food was begun on the third day, following an enema. On the fourth day both began to bend the affected knee; oedema steadily diminished. Urine, tested daily, revealed nothing abnormal, and the output was never less than 75% of intake. As in cases reported in the *Journal* of March 22, the non-protein nitrogen was estimated on both, and was found to be well within the normal limits—25 mg. per 100 c.cm. in one and 27 mg. in the other.

By the end of the week the oedema had practically disappeared; there had been no vomiting, the bowels were acting normally, blood pressure in both was 148/85, and fluid output was equal to intake. After ten days all gangrenous patches were separating at the edges, leaving clean granulating surfaces underneath. No oedema was present. Slight movement of the foot was noticed.

At this stage Miss A. D. showed evidence of slight left ulnar nerve injury with some median involvement, only fingers affected; the hand was splinted in dorsiflexion. At the time of writing, thirteen days after admission, this is already showing signs of clearing up, and the general condition of both patients is excellent. Stringent precautions have been taken all along, no visitors having been allowed until the eleventh day and the cradle lamps still being in use. Both are eating and sleeping normally, and there has been no change in their mental condition. They have not talked much of their experiences, nor have they as yet been questioned.

Commentary

These two cases raise several points of both general and medical importance. I have suggested to the municipal authorities that it would be of great advantage if some form of sound-detector could be employed on the site of a disaster as early as possible. Both patients state that whereas they could hear everything going on above them—and Miss F. B. says that her father was alive for two days and Miss A. D. that the child lived for nearly three days—their voices were not heard until sufficient debris had been removed nearly four days afterwards. The reason for and advantages of a sound-detector are therefore obvious. I suggest also that rescue work should be carried out on the assumption that people are alive though buried, and that work should be done in relays without ceasing. All ambulances should normally carry hot-water bottles (I used three of my own on this occasion) and six feet of rubber tubing with feeding-cup.

The important medical points that occur to one, bearing in mind the positions in which the patients were found and the length of immobility, are: (1) The severe limitation of oxygen supply, and the lack of fluid intake, both acting together, failed to produce the obvious mental and physical reactions. (2) The extraordinarily good condition of the skin and the warmth of the extremities. (3) The absence of irritation conjunctivitis. (4) The clearness of the air passages and the absence of gritty lungs. (5) The comparatively mild nerve-pressure paralysis.

I believe a doctor working in conjunction with the rescue squad is the ideal arrangement when there is any chance of rescuing people alive, and would stress the importance of some form of sound-detector and my belief that the dangerous period after prolonged burying is that between the moment when exposure takes place and the patient's arrival in hospital. Thus treatment on the lines already indicated should be instituted during the actual rescue. Lastly, I would support Prof. H. A. Harris in his criticism of over-treatment. Briefly put, the treatment of "crush cases" should provide a maximum of rest, both physical and mental; a maximum of warmth, both external and internal; and a minimum of interference.

I would like to thank my resident, Miss Walsh, and the nursing staff of the hospital, for their whole-hearted co-operation.

Clinical Memoranda

Oestradiol Benzoate in Hypoglandular Rheumatoid Arthritis

During the past season a number of female patients with rheumatoid arthritis had very limited time to complete a satisfactory course of spa treatment owing to home duties of an urgent nature. Six weeks would be an ideal course for the average case, but some patients could spare only two weeks, and less than three is of very little use.

In the early spring of 1940 I noticed that those who were taking small doses of oestradiol preparations or the synthetic substance stilboestrol for menstrual disorders showed remarkable improvement in coexisting hypoglandular rheumatoid arthritis. In all these cases I decided to supplement treatment with intramuscular injections of oestradiol benzoate in oil. The results have been beyond all expectation, and I now use this method as a routine. Many patients felt distinct improvement within twelve hours of the injections.

The cases varied from slight periarticular thickenings of the hands to marked multiple thickened joints. In one there was complete ankylosis of the knee-joints, but the general health greatly improved. Two patients had multiple thickened joints, pathological deformity of hands, knees, and feet, and very poor mobility. They were becoming totally disabled and were very depressed, and considered their cases to be hopeless. After several weeks' treatment all the mild cases cleared up completely. The two advanced ones made a remarkable recovery. One is almost free from any signs, and the other patient is fit for light occupation.

Oestradiol benzoate has been of great benefit in combination with spa treatment owing to the fact that patients suffering from depression often state that they have a feeling of general well-being during the first day of its use. Injections were given twice weekly intramuscularly in addition to the spa treatment. A high dosage of 50,000 units was used in severe cases, and 10,000 units and upwards for milder ones. Ampoules representing both strengths or a bulk quantity can be used, and a 1-inch-long No. 21 needle was found suitable. Injections were made into the deltoid and were quite painless. The syringe can be kept free from any moisture in a pocket spirit case containing 5% lysol added to the spirit. It is very important to warn these patients, irrespective of age, not to be alarmed if a menstrual cycle begins some days or weeks after the injection. The flow, if troublesome, can be regulated by giving calcium and ergot preparations, but this was not required, or if the cycle date is noted a corpus luteum preparation could be given daily for a week before the next cycle. This preparation is costly and its use in rheumatoid arthritis may not be of any particular advantage.

Oestradiol benzoate is tolerated by all, and has no harmful effects even in pregnancy. Male cases of rheumatoid arthritis also respond to oestradiol benzoate injections, but I have used only a short course on a few cases in view of any disturbance to the prostate gland. Stilboestrol can be used as a substitute but in a few cases nausea was complained of even with a small dosage. A recent improvement has been made to stilboestrol which obviates any nausea.

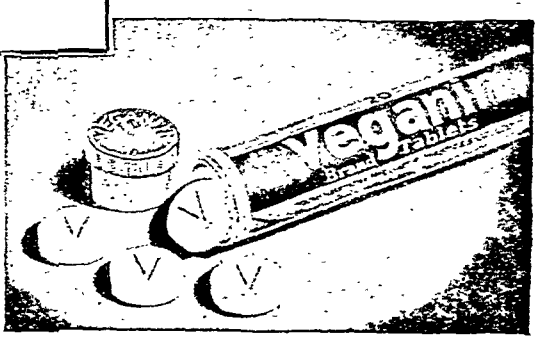
Strathpeffer Spa, Ross-shire.



"A pig in a poke"

Your patients may be daily buying symbolic pigs in hypothetical pokes. In your desire to save their pockets you may be prescribing a product that is offered as "just as good and cheaper than Veganin."

Veganin has no substitute in quality; it is the achievement of long experimentation. The demand was for an analgesic assuring safety with prompt efficacy; one which the physician could prescribe with that absolute confidence he gives only to a standard product which never varies in character or quality.

Veganin stands unique as an analgesic, sedative and antipyretic bearing a brand name which is pledged to the maintenance of the highest standards of uniform production.

Supplied in tubes of 10 and 20 tablets: quantities of 100, 500 and 1,000 tablets for dispensing.

WILLIAM R. WARNER & CO., LTD.
POWER ROAD CHISWICK LONDON, W.4.

AT THE MENOPAUSE

"High Doses of Oestrin are usually unnecessary, at any rate for the commoner menopausal symptoms—such as vasomotor disturbances — and consequently oestrin injections are, fortunately, seldom required. It has been my practice to begin with doses of about 500 I.U. daily by mouth. If this does not control the symptoms the dose is raised to 1,000 . . . this is usually completely effective. There are, of course, certain more severe sequelæ of the menopause, which demand much higher doses . . . Pruritis, Kraurosis, Leukoplakia vulvæ, fall into this class and, provided sufficiently high doses are given, the results are little short of miraculous."

Reviews

PRACTICAL SURGERY

A Short Practice of Surgery. By Hamilton Bailey, F.R.C.S., and R. J. McNeill Love, M.S., F.R.C.S. Fifth edition. (Pp. 1,015; 880 figures. 30s. net.) London: H. K. Lewis and Co., Ltd. 1941.

New editions appear despite war and paper shortage, and perhaps it is as well, since the authors of *A Short Practice of Surgery* tell us in their preface to this fifth edition that surgery progresses with such rapidity that they have found deletions and additions necessary in every chapter of the previous edition. The biographical footnotes continue to be an attractive feature of this book, but some are incompletely dated or need revising (e.g., J. Hogarth Pringle, p. 62; E. C. Davidson, p. 78; and Cushing, p. 600). Kocher's name appears with bones and joints, but should also appear in the chapter on the thyroid, and Sistrunk's should be attached to the operation shown on page 199. Carr is mentioned on page 769 and without the usual biographical reference, but the authors may not have seen a note on Carr's splint which appeared in the *Irish Journal of Medical Science* for April, 1940. The chapters on neurosurgery would benefit with still more revision: statements such as medulloblastomata being irremovable and catgut being used for dural closure and the bone flap taken out to decompress irremovable tumours would not meet with the agreement of most neurosurgeons. Elsewhere exception might also be taken to the dogmatic statement that the only effective treatment of Banti's disease is splenectomy. On the whole, however, revision has been good, and the book is sufficiently modernized to include a picture of a bomb fragment producing a comminuted fracture and of gas gangrene in a man wounded at Dunkirk. The new edition should ensure the continued popularity of this textbook.

EDUCATION OF EXCEPTIONAL CHILDREN

The Education of Exceptional Children: Its Challenge to Teachers, Parents, and Laymen. By Arch O. Heck, Professor of Education, College of Education, the Ohio State University. (Pp. 536; illustrated. 26s.) London: McGraw-Hill Publishing Company, Ltd.

One of the most difficult problems of education is to provide for those children who for one reason or another cannot or do not fit in with the majority of their fellows. Special education is expensive both in money and in personnel, and the present volume is an effort to evaluate what has been done in America and what ought to be done if exceptional children are to be provided for adequately and successfully.

In the first section what are called socially handicapped children are considered. These are the truants and delinquents, and in the course of the discussion a brief and rather inadequate survey of the causes of these behaviour reactions is given, but the main theme is how the State provides against these difficulties. First, what can be done by teachers and others in the ordinary school is dealt with, then special day schools are described and the advantages and difficulties of parental or, as we should call them, residential schools are discussed. These all cater for the child before he comes to the courts. The State training schools are then referred to, and the change of conception from a penal to an educational character of such institutions is noted. Several such schools are described.

The next section deals with the cripple child, and since the cripple has the same ambitions, desires, and mental abilities as has the average child he is entitled to equal educational opportunities, though his educational programme must recognize handicaps, while initiative and self-reliance should be specially encouraged and he must be kept at school just so long as school will help him intellectually, physically, and especially emotionally. Next the costs and difficulty of providing the necessary equipment for a cripple school are discussed and representative schools are described. Similarly, problems connected with the education of blind children, children with defective vision, deaf and partially deaf children and those with defective speech, or especially delicate children are discussed.

The third section approaches, along similar lines, the problems of the mental defective, which are well known to us in this country, but there is also a discussion of the proper provision for the optimum education of specially gifted children. This movement has aroused much prejudice and opposition in the United States and has scarcely been considered in this country at all, but it has some obvious advantages if the costs could be met and the sentimentalism which will help the defective but do nothing for the talented can be overcome. The last section takes up financial and administrative questions; it is naturally concerned with conditions in America and therefore less applicable to this country.

Although this is primarily an educational book of reference, it ought to be of interest to the medical profession, since proper education of children who are medically unfit is one of the prime essentials in their care.

THE CARDIOGRAM IN CONGENITAL HEART DISEASE

The Electrocardiogram in Congenital Cardiac Disease. A Study of 109 Cases, 106 with Autopsy. By Maurice A. Schnitker, B.Sc., M.D. (Pp. 147. 16s. 6d., or $3.00.) Massachusetts: Harvard University Press; London: Oxford University Press. 1940.

In his book on the cardiogram in congenital heart disease, which is stated by the publishers to be the first of its kind, Dr. Maurice Schnitker has attempted something which presents great difficulties. In the first place, the lesions are often multiple or complicated by acquired disease; and, secondly, post-mortem examination is essential to establish the exact nature of the defects. It is almost impossible for a single observer to see a sufficient number of cases and follow them to necropsy, and Dr. Schnitker's series of 109 cases (106 with necropsy) are largely collected from the literature, which, however unavoidable, does detract from their value. The cases are classified as acyanotic, late cyanotic, and permanently cyanotic, and a general description of each lesion is followed by fairly detailed clinical and post-mortem reports and illustrations of the corresponding cardiograms. This compilation will have its uses, but it also emphasizes the obscurity and complexity of its subject.

ACTIONS AND USES OF DRUGS

Synopsis of Materia Medica, Toxicology, and Pharmacology. For Students and Practitioners of Medicine. By Forrest Ramon Davison, B.A., M.Sc., Ph.D., M.B., Assistant Professor of Pharmacology, School of Medicine, University of Arkansas, Little Rock. (Pp. 634. 25s.) London: Henry Kimpton. 1940.

Prof. F. R. Davison has modestly entitled his work *Synopsis of Materia Medica, Toxicology, and Pharmacology*: it is true that the volume is of relatively small size, but since it contains well over 600 pages of small print it is, in fact, a very comprehensive textbook. It has been written from the clinical aspect and is concerned with the properties of those drugs that are of

practical importance. These are classified according to the character of their actions; the pharmacological effects, therapeutic uses, and toxicology are described in each case, together with any pharmaceutical properties that are of therapeutic interest. Thus the book covers a very wide range, for in addition to the pharmacology of medicinal drugs it gives a description of the toxicology of the more important poisons, such as lead, arsenic, and phosphorus. The wide range covered causes the description of pharmacological actions to be somewhat brief, and some of the statements made are open to question. On the other hand, Prof. Davison gives information about a remarkably large number of subjects and pays particular attention to recent advances in therapy. For example, accounts are given of the therapeutic uses of snake venom, heparin, and sobisminol.

The close printing of the volume makes it difficult to read continuously, but it constitutes an excellent work of reference, and its value in this respect is increased by the provision of selected references to recent literature.

Notes on Books

A Review of the Psychoneuroses at Stockbridge, by GAYLORD P. COON, M.S., M.D., and ALICE F. RAYMOND, A.B., is published in Massachusetts by the Austen Riggs Foundation. Stockbridge is a residential home for psychoneurotics which was run by Dr. Austen Fox Riggs, to whom this book is in some respects a tribute. The method of treatment is described as re-education and persuasion, and of later years some superficial analysis has been employed. After their first treatment the patients go home on trial visits, return for follow-up visits, and contact is retained by correspondence. In the twenty-five years of its existence some 5,300 cases were noted, but a sample of 1,060 cases only were chosen for this study. These were chiefly anxiety cases, and of these the history of ninety-two is summarized. Statistical data of all sorts of factors in the rest is given, and although the method of treatment is accorded considerable approbation the results are not particularly striking, 30% being considered to be much improved, 28% improved, 6% unimproved, and 36% unknown. Among various appendices one gives a sort of survey of psychology which is handed in pamphlet form to the patient for his study at leisure. While this book contains a collection of odd statistical records, some of which may be useful for reference, it cannot be regarded as very interesting or very instructive to the ordinary reader.

Textbooks on histology and embryology are largely written for the use of medical students, but there is another class of readers who require a practical knowledge of these subjects—namely, science students who are preparing to teach elementary biology in schools. The small book on *Practical Histology and Embryology*, by NELLIE B. EALES, D.Sc. (Macmillan, 3s. 6d.), is admirably adapted for this type of student. Its general trend is well indicated in the opening sentence of the author's preface: "There is always satisfaction to be derived from a well-stained section or slide mount, and to make it for oneself gives even greater pleasure." The book shows the way to prepare such specimens, and briefly describes the elementary principles concerned in interpreting the appearances which are seen when the sections have been mounted and are viewed under a microscope. In the section on embryology there are a few outline drawings which accurately represent certain stages in the development of fish, frog, chick, and rabbit embryos. One would like to see more of these, and also some notes on the use of projection apparatus, with a view to encouraging the practice of making accurate records of work accomplished in the laboratory. The book represents the work of an experienced and devoted teacher, and merits a wide circulation.

No. 18 of the *Proceedings of the University of Otago Medical School* has been published at Dunedin under the editorship of Prof. J. B. Dawson. It consists of reprints of papers which have appeared in the *New Zealand Medical Journal*, the *British Medical Journal*, and other journals during 1939-40; also Prof. D. W. Carmalt Jones's address at the graduation ceremony in May, 1939. The volume may be consulted in the Library of the British Medical Association.

The University of California has published its *Hospital Formulary and Compendium of Useful Information* in a form convenient for the pocket. Doubtless it will often be found there, for the amount of helpful information compressed into this slender volume is indeed remarkable. Out of its 255 pages only 16 are devoted to the hospital prescriptions, the remainder ranging over such diverse fields as vaccines, diet tables, infant welfare, laboratory procedures, and common emergencies. Truly a *multum in parvo*. It is published at $2.00 by the University of California Press, Berkeley and Los Angeles.

Preparations and Appliances

X-RAY STRETCHER OUTFIT

An *x*-ray stretcher outfit has been introduced by Philips Lamps Ltd. (Century House, Shaftesbury Avenue, W.C.2) with the object of reducing the amount of handling to which acute cases are subjected in the journey to and from the *x*-ray room. With this stretcher the patient undergoes one move only—carried out at the bedside by the nursing staff. The outfit consists (1) of a special form of wheel stretcher suitable for use as an *x*-ray table, and (2) of a pedestal Bucky unit to which the stretcher can be coupled so that the two together form a horizontal radiographic Bucky couch, and only the tube stand or mobile unit is needed to complete the installation. In the *x*-ray department the stretcher with the patient already in position is wheeled over the pedestal Bucky, which is raised into contact by pressure on a foot pedal, and the radiograph is then made. The apparatus can be adapted for other uses: with the completion of a head lamp the pedestal Bucky becomes a convenient radiographic apparatus for the skull, and with the addition of a back rest it can be made to serve as a pelvimetry outfit. Every detail of construction has been thought out to give the utmost facility and convenience, especially in a casualty department working under pressure.

ASCORBIC ACID FOR INFANTS

Infant "celin" tablets (Glaxo Laboratories Ltd.) contain 5 mg. ascorbic acid, a quantity which the vendors state to be equivalent to the content of two teaspoonfuls of orange juice. Messrs. Glaxo provide a pamphlet which explains the necessity for an adequate supply of ascorbic acid in infant feeding, and point out that deficiency of this vitamin is likely to be caused by the scarcity of oranges. The tablets are sold at 12s. per 1,000, or 2s. 3d. per gramme of ascorbic acid, a price which is less than the cost of an equivalent quantity of orange juice.

OXYLAN FOR OXYURIASIS

"Tabloid oxylan" (Burroughs Wellcome and Co.) has the chemical constitution *p*-benzylphenyl carbamate. It is recommended for the treatment of oxyuriasis (threadworm infestation) in children and adults. The makers state that it is designed to replace a preparation of foreign origin. The compound is stated to be efficacious and to be free from undesirable side-effects. The adult dose is 7½ to 15 grains (1/2 to 1 gramme).

SYNTHETIC LEMON POWDER

Crookes's lemon powder (synthetic) is a powder which provides a synthetic lemonade. One teaspoonful in a fluid ounce of water provides a drink which contains 10 units (0.5 mg.) of ascorbic acid and 80 mg. of citric acid per mille. This is similar to the content of these substances in undiluted lemon juice. The makers point out that the absence of lemons from the English market has created a need for a lemon powder which is an adequate substitute for lemons in regard to its content of ascorbic acid.

British Medical Association

CLINICAL AND SCIENTIFIC PROCEEDINGS

Oxford Division

Two general meetings of the Oxford Division have been held at the Radcliffe Infirmary, Oxford, during recent months. Non-members and clinical students attended, and Dr. W. STOBIE presided on both occasions.

PRINCIPLES OF RESUSCITATION

At the first meeting Prof. L. J. WITTS opened a discussion on the principles of resuscitation. He first said that he agreed with Mr. Rock Carling that resuscitation was primarily a physician's task. Referring to the Oxford area, he said that in the event of an air attack 500 casualties might reasonably be expected, and the Radcliffe Infirmary might have to cope with 250 casualties in twenty-four hours. Eighty beds could be made available in about twenty minutes, with more within twenty-four hours. The Infirmary could deal with 100 severe casualties in about twenty-four hours, given that the four available surgical teams might each require one hour's operating time per casualty. There need be no desperate hurry to get most of these patients to the theatre. They must first be made warm and rendered fit for surgery: but there must, of course, be no undue delay. The resuscitation and pre-operative measures should be regarded as one entity. Case notes on each patient were desirable, and students were being trained to take notes so far as possible as usual. Traumatic shock was due to loss of fluid from the circulating blood. This could be caused by (1) exudation of plasma into tissues—for example, in patients suffering from burns or crushed under masonry; (2) loss of blood; and (3) a combination of both.

Treatment must be directed to the following. *(a) Fluid Replacement.*—At least forty-eight bottles (two-pint) of blood or plasma per 100 casualties would be required. Plasma kept better than blood and required no grouping, but it was more expensive, because three bottles of blood were required to produce one bottle of plasma. Fluid by the mouth could be given as hot tea, milk, or beer. *(b) Warmth.*—This could be given by the electric cradle, hot-water bottles, etc., but its exact application had not yet been fully worked out. *(c) Relief of Pain.*—In casualties requiring operations this concerned the anaesthetist. Points of importance were the time of the operation, and the fact that casualties with head injuries should not usually be given morphine. *(d) Oxygen.*—The patient should get the highest possible concentration. The tissue anoxia was due to the feeble circulation in shock; therefore as much oxygen as possible should be dissolved in the plasma itself in addition to that in the corpuscles.

PREMEDICATION FOR ANAESTHESIA

Prof. R. R. MACINTOSH, discussing relief of pain and premedication from the anaesthetist's point of view, said that patients did not all start from the same metabolic level when being anaesthetized. Youth, pain, fear, fever, and a quality of resistance known to the Americans as "sthenicity" all tended to raise patients above the hypothetical starting-point of anaesthesia. The aim of sedative premedication should be to lower each patient as nearly as possible to this common hypothetical starting-point. Drugs used for this purpose acted mainly by lowering the basal metabolic rate. They should be given if possible one and a half hours before the anaesthetic. Atropine or hyoscine was also given to inhibit bronchial secretions stimulated by anaesthetics such as ether; atropine began to act in about ten minutes from injection subcutaneously. He suggested that a label should be fixed to each casualty while in the ward stating the name, the pre-operative drugs given, and the time they were given. Post-operative drugs could be ordered on the back of the label—for example, "1/6 grain morphine if in pain or restless." The "tonsil" recovery position was the best post-operatively. The patient should not be left on his back owing to the risk of respiratory obstruction by the tongue.

Dr. FLETCHER demonstrated the bottle used by the Oxford Blood Transfusion Service for the recipient; this was supplied with sterile needle ready for use. If venepuncture was difficult, he said, it was better to cut down on the vein at once. Difficulty in getting the blood to flow in shocked patients might be due to spasm. A Higginson syringe or a sphygmomanometer bulb and cuff attached to the air inlet of the bottle could be used to raise the pressure and counteract the spasm.

Dr. MOLE demonstrated apparatus for oxygen therapy. He said that some type of flowmeter was necessary. A Boyle's type bubble bottle gave this in its simplest form and was fairly satisfactory. Methods of administration were: (1) The simple funnel and tube; this was practically useless. (2) An anaesthetic face-mask, which could be used for short periods but was distressing to the patient. (3) Nasal catheters, which were fairly satisfactory; extra holes in the catheter increased its effectiveness. The catheter must be lubricated and passed far enough into the nasal cavity along its floor. The correct length to insert was the distance between the nostril and the lobe of the ear; this was about three or four inches. A catheter in both nostrils was more effective than one. The spectacle frame was a useful carrier for two catheters. Three litres per minute could be delivered comfortably by one nasal catheter; this would raise the alveolar oxygen to 30%. Five litres per minute could be administered with two catheters, thereby raising the alveolar oxygen to 45% or 50%. (4) The B.L.B. mask, which was the most efficient and comfortable method. A nasal or an oro-nasal type could be used. With this mask the alveolar oxygen could be raised to 90% by using a flow of six to eight litres per minute with the air-holes closed. This mask could also be used to relieve surgical emphysema or intestinal distension by replacing the relatively non-absorbable nitrogen by oxygen.

A discussion followed in which Mr. G. R. GIRDLESTONE stressed the importance of speed in getting casualties to the theatre in less than six hours. He also suggested experiments to see whether organisms in wounds could be kept quiescent by means of ice applied locally while the patient was treated by warmth and restoratives.

RECENT DEVELOPMENTS IN IMMUNIZATION

Prof. G. S. WILSON, in a talk on modern developments in immunization methods, said that in considering any prophylactic inoculation the following principles must be remembered. (1) It was not worth while vaccinating patients against a disease unless that disease was serious enough to warrant it. (2) The disease must be common enough to make it worth while. (3) The vaccine must be of proved potency. (4) Reaction to the vaccine should be relatively mild in comparison with the disease itself. If these criteria were accepted, chicken-pox and rubella could be ruled out at once. Influenza could also be ruled out because the vaccine was still experimental; the disease—probably due to a virus—was not a bacteriological entity. Scarlet fever immunization was unsatisfactory, the reactions being often as severe as the disease. This left, in peacetime, diphtheria, measles, whooping-cough, and small-pox, to which in wartime could be added enteric fever and tetanus.

Diphtheria.—The protection given by immunization was very good. The disease was uncommon before the first year of life, and the maximum mortality occurred between 5 and 10 years. It would be possible to eliminate the disease if all the children from 1 to 15 were immunized; it could be regarded as satisfactory if 90% or more of this age group were inoculated. The immunity produced was antitoxic, not bactericidal; therefore it was important to immunize all children, as the immunized might become healthy carriers and prove a source of danger to the non-immunized. A.P.T. was the most satisfactory agent, but he did not recommend the one-shot method. Two injections acting as primary and secondary stimuli were necessary. The second injection should never be given under four weeks. Prof. Wilson advised 0.1 c.cm. for the first and 0.3 c.cm. for the second injection. This would make 98% to 100% of children Schick-negative. Reactions were rarely severe under 15 years, though there might be local redness, swelling, and tenderness. This method was

not advised for adults, as severe reactions might occur. If all pre-school and school children were immunized the adults need not be worried about. Prof. Wilson suggested as a complete course that the first two injections should be given before school age, followed by 0.3 c.cm. on going to school, and 0.3 c.cm. about the age of 10. A sudden outbreak of diphtheria at a school could be controlled by giving each child 500 units of special refined antitoxic serum (0.1 c.cm.) in one arm, and 0.1 c.cm. of A.P.T. in the other at once. All should have throat swabs taken and all carriers found should be isolated. The school could return the following day. Four weeks later all should be given their second dose of A.P.T. (0.3 c.cm.), and after a further two weeks the carriers could be allowed to return.

Measles.—The mortality was maximal in the second year, and 85% of deaths occurred in the first five years. Two methods of prophylaxis were available: (*a*) convalescent serum and (*b*) pooled adult serum; the former was about twice as potent as the latter. For complete protection the serum should be given within three days of infection; for partial protection, which was usually preferable as it gave permanent immunity, the serum was delayed to between the third and fifth days, or else half a dose of serum was given.

Whooping-cough.—The maximum mortality was in the first year. Large doses of vaccine were required for immunization, starting at about 10,000 million, three or four doses being given at weekly intervals from the end of the second or third month of life. The duration of protection was unknown. This injection could be combined with diphtheria immunization.

Enteric Fever.—This was not normally common, but wartime increased the risk of infection. Vaccines gave substantial, but not complete, immunity. Reactions might be severe in the first three days following injection. A new vaccine containing alcohol instead of phenol was being produced which was more potent and after which there was less reaction. In starting general immunization Prof. Wilson advised concentrating on those persons most likely to become infected—for example, doctors, nurses, A.R.P. workers, etc. The Ministry of Health had advised against general immunization at present unless an epidemic appeared. Prof. Wilson felt that the risk of an epidemic occurring in Oxford was probably not very great, but that it might be worth while to immunize the population gradually.

Tetanus.—The risk of infection was very slight in peacetime, but was great in wartime. A toxoid similar to that for diphtheria was now available (formol-precipitated), two doses of 1 c.cm. being given with six weeks' interval. This produced a considerable degree of immunity, but as anti-tetanus serum was given to every casualty as a routine it was at present doubtful if it was worth immunizing people as well.

NUTRITION

At the second meeting Dr. H. M. SINCLAIR opened a discussion on nutrition. After a brief review of research work on vitamin deficiency and some reference to the value of protein, fat, and carbohydrate in proper proportion in the diet, and also of minerals, especially calcium and iron, he said that there was much public ignorance about the importance of a properly balanced diet. The idea that orange juice supplied all that was necessary in the way of vitamins was common. He then discussed the importance of the fat-soluble vitamins A, D, E, and K, and of the water-soluble vitamins C, P, and the B complex. War conditions increased the likelihood of deficiency arising from the severe restrictions on fats and raw fruit. The simplest and cheapest way of avoiding such deficiency was to take one of the various vitamin concentrates on the market. Deficiency of one vitamin alone practically never occurred. In reply to a question as to how much harm could be done by the ingestion of excess of vitamins, Dr. Sinclair said that only two of them—vitamin D and nicotinic acid—were toxic if taken in excess. But very large amounts were needed to produce symptoms of poisoning. A few years ago some deaths were reported from calcification of the breast and blood vessels in children who had been given halibut-liver oil in doses suitable for cod-liver oil. It had not been realized at the time that halibut-liver oil contained much more vitamin D than cod-liver oil.

Nova et Vetera

SOME TEXTBOOKS OF FIFTY YEARS AGO

Dr. JOHN R. KEITH writes from Southsea:

I was greatly delighted by the Nova et Vetera article bearing the above title (March 15, p. 413). It recalled to memory many pleasant hours spent in reading several of these books and others suggested by them. For example, what a charming writer was John Milner Fothergill, who combines poetry and anecdote with invaluable clinical information. His *Physiological Factor in Diagnosis* is of the highest value; so, too, is *The Antagonism of Therapeutic Agents, and What it Teaches.* Also his brochure, "What to Ask," is what every young general practitioner ought to read if it is still in print. Many years ago I wrote an article on the value of perusing medical literature, and among the books I mentioned was King Chambers's *Clinical Lectures.* I sent a reprint to Sir William Osler, who acknowledged it by an appreciative postcard, in which he said that King Chambers's *Renewal of Life* was a favourite book of one of his teachers in Toronto. Among other writers of medical books of bygone days which may be read with much profit are Furneaux Jordan, the author of *Surgical Enquiries* and his Hastings Essay on Shock; and Thomas Inman, whose monograph *On Myalgia* is one of the most helpful medical books I have ever read. With regard to Inman, Cameron Gillies in his *Counter-Irritation* writes: "If first-class men produce first-class work only to lie buried in dusty heaps of tomes in out-of-the-way corners of our libraries and museums, it is not surprising that medical progress is so slow and uncertain." Highly useful to the general practitioner are Peter Hood's *On Bone-setting* and Wharton Hood's *Treatment of Injuries by Friction and Movement.* A medical man well known to me was once condemned to an inactive life for several weeks through ignorance of the existence of this book. He had ruptured several fibres of one of the gastrocnemii. Had he known of this volume he would have been able to continue active medical practice without difficulty. Another useful book concerning injuries is Anglin Whitelock's *Sprains and Allied Injuries of Joints,* which contains what I have found to be the best method of reducing dislocated semilunar cartilages. I must not omit mention of Ramsay Smith's *Angio-Neurosis,* which deserves a better fate than being allowed to lie in a first edition. I cannot conclude without a reference to G. H. Sutton's *Lectures on Pathology,* upon which Morley Roberts bestows a high eulogium.

In his interesting Cameron Prize Lecture, delivered last October (*Edinb. med. J.*, 1941, **48**, 1), Prof. E. C. Dodds remarks that few commentators realize that the introduction of aspirin in 1899 marked the start of a new era in medicine. The preparation by von Baeyer of a pure preparation of acetyl-salicylic acid showed that the chemist could synthesize new compounds that proved to be more effective than those occurring naturally. The Germans, Prof. Dodds remarks, were quick to understand the significance of this discovery, and the production of synthetic compounds with specific therapeutic activities was carried out by many scientists. "The years that followed were crowded with successful work in this field, carried out almost entirely by chemists working for the big German chemical firms." Before describing his own work on stilboestrol Prof. Dodds touches briefly on some of the earlier attempts at opotherapy. During the sixteenth and seventeenth centuries physicians were in the habit of prescribing Egyptian mummies as opotherapeutic agents. The treatment became so popular that "the supply of the genuine article ran out, and a new industry to manufacture Egyptian mummies sprang up." The industry was centred in France, where the bodies of executed criminals and slaves were used for the synthetic mummies.

BRITISH MEDICAL JOURNAL

SATURDAY APRIL 19 1941

VACCINE FOR TYPHUS

Following the last world war and its aftermath, which brought malnutrition and poor living conditions in vast areas, influenza swept round the world and exanthematic typhus assumed epidemic proportions in several countries. Recently there have been reports of typhus fever among the Italian troops in Albania, and small epidemics among the civilians in Poland. Now the effects of the civil war in Spain are bearing the same fruit. So far some 300 cases of exanthematic typhus with 27 deaths are said to have occurred in Madrid, and there have been cases also in Seville, Granada, and Almeria. There is a scarcity of washing soap as well as of food, and the Madrid authorities are taking vigorous action in dealing with such possible carriers of lice as *mendicants and loiterers*. This epidemic has provided an opportunity for a thorough trial in the field of the latest and most promising vaccine yet evolved against the typhus infections. Hitherto, either living attenuated or inactivated typhus rickettsias have been used as a vaccine. The French have employed a vaccine of living murine rickettsias in Morocco and Tunis on a large scale. This may be dangerous in areas where an epidemic is present, or where there is overcrowding, for lice may become infected by feeding on vaccinated individuals while they still have living rickettsias in the circulation. There is also no definite proof that the murine virus vaccine completely protects against the exanthematic strain. When killed rickettsias are used very many must be injected for the vaccine to be effective. Weigl's vaccine,[1] which was widely employed, consisted of a formalinized suspension of guts of lice infected with rickettsias by inoculation per rectum. This entailed the keeping of an enormous louse population and was a laborious procedure. The recently evolved vaccine of Durand and Giroud,[2] which is much simpler to prepare, consists of an almost pure suspension of formalinized exanthematic typhus rickettsias obtained from the lungs of mice inoculated intranasally. Unfortunately four or five inoculations at weekly intervals are necessary.

In an attempt to produce large numbers of rickettsias Zinsser and his colleagues[3] have used chick embryo tissues mixed with the rickettsias and spread on agar slopes. This yields a large number of rickettsias, but is not as simple as Cox's method[4] of injecting the rickettsias directly into the egg yolk sac, which gives an even better yield. Fertile eggs, which have been incubated six or seven days at 39° C., are inoculated into the yolk sac and incubated at 37° C. until the death of the embryo, which usually occurs in five to seven days. The yolk sac is then removed with sterile precautions, ground in a mortar, and suspended in saline, and a nearly pure suspension of rickettsias is obtained by differential centrifugation. Phenol and formalin are added and the vaccine is stored at 2° C. Smears are made from the yolk sac when it is removed to verify the presence of the rickettsias. After trying various methods Gear[5] in Johannesburg found this to be the simplest, one person being able to turn out large quantities in a short time. If desirable, murine and exanthematic rickettsias can be grown separately and mixed in the final vaccine. This vaccine prepared by Cox, as well as fresh vaccine made locally, is being used in Madrid. Three inoculations are given at weekly intervals with little ensuing reaction. A similar vaccine has already been tried out in Peking, but results are not yet available. In view of the suggestion of Pijper and Crocker[6] that the South African epidemic typhus may not be identical with the classical European strain, it will be interesting to hear if there is any difference between the results with the American vaccine and that prepared locally, presumably from a strain recently isolated in Spain. Although British troops in Russia and Serbia in the last war fought side by side with the local soldiers, among whom typhus was very prevalent, few of them contracted the disease, due largely to the vigorous delousing methods carried out. Nevertheless it is comforting to know that, if necessary, there are possibilities of readily producing an efficacious vaccine in large quantities.

It is a far cry from Spain to New Guinea, where a form of endemic typhus exists, though none has been reported yet from either Papua or Dutch New Guinea, which adjoin it. Gunther,[7] in reviewing the disease there, describes the cases as clinically resembling those of Japanese river fever and having agglutinins for *Proteus OX K* in their serum. It is practically confined to the adult white males, and among the diseases attacking whites in New Guinea ranks second only to blackwater fever in importance. Since 1934 there have been seventy-four cases with nine deaths in the Molobe district. The likely vector is a larval trombidiid mite, *Trombicula minor* Berlese 1905, and a bandicoot, *Echymipera cockerelli* Ramsey 1877, is probably the reservoir of the disease. Lewthwaite and Savoor[8] have shown that the scrub typhus of Malaya and the mite fever of Sumatra are identical with Tsutsugamushi disease of Japan, and the disease in New Guinea apparently belongs to this group. Though the Japanese have used so-called attenuated or less virulent strains for immunizing, there is no killed vaccine available against these diseases, in which the mortality rates vary widely, with 4.5% in the Malayan fever, 40% of Europeans and 5% of Japanese in the Sumatran fever, and 40% for the Japanese river fever. It is to be hoped that the embryo chick and its membranes may soon be found to be a satisfactory culture for the mite-borne rickettsias, as it has for the louse-, flea-, and tick-borne varieties.

In the Far East a further step has been made in solving the rare group of undiagnosed fevers in Australia. In 1935 Langan and Matthew,[9] and Unwin,[10] reported that serum of some patients with

"coastal fever" of North Queensland agglutinated *Proteus XK*. Now Heaslip[11] has isolated from numerous cases of coastal fever a pleomorphic organism, usually seen as a Gram-negative bacillus showing bipolar staining or as a Gram-positive anthrax-like bacillus. It grows readily on, or in, artificial media at temperatures between 20° C. and 30° C., but will not multiply appreciably at 37° C., when the media are directly inoculated with the patient's blood. Transmission appears to be by a vector which is either a mite, which seems the most likely, a mosquito, or a tick. It is possible that droplet infection could occur, for the organisms are present in the sputum if the patient develops the specific bronchitis which may be a symptom of the disease. The organism has also been found in the blood in cases of typhus. It is present in 70% of captured rats and bandicoots in the district. The disease occurs all through the year, but the heaviest incidence follows immediately after the rainy season. At this time there is a seasonal increase in the number of mosquitos and larval mites, and as a result of flooding of fields the rats are driven closer to human habitation. Heaslip believes this probably is the same organism as that which Anigstein found in cases of typhus in Malaya in 1933.

TOXICITY OF STILBOESTROL

English clinical experience has not for the most part found that the toxic side-effects sometimes associated with the administration of stilboestrol are of such a magnitude or severity as to contraindicate the use of the drug. In America, however, there has been more hesitancy about the acceptance of the synthetic product in place of the natural hormones in spite of the advantages offered by the oral potency and relative cheapness of the former. The reports submitted to the Council on Pharmacy and Chemistry of the American Medical Association were not unanimous enough on the question of toxicity to allow the Council to recommend the recognition of stilboestrol or its inclusion in *New and Non-official Remedies* until further experimental trials had been undertaken. The report which emphasized the toxicity more particularly was that of Shorr, Robinson, and Papanicolaou,[12] who found that only 20% of their forty-four patients exhibited no toxic symptoms. The rest suffered from some or other ill effect, gastro-intestinal disturbances such as nausea and vomiting being the most common. Other symptoms noted were lassitude, cutaneous rashes, acute thirst, and a psychotic reaction in one case. The evidence of toxicity in the other two reports on which the Council decision was reached was by no means so striking. Buxton and Engle[13] had laboratory evidence of toxicity (albuminuria) in only one of their sixteen cases, and the nausea and vomiting they occasionally found were not thought by them to be a contraindication to the use of stilboestrol. MacBryde, Freedman, and Loeffel[14] studied thirty-seven patients and reported vomiting in only three, although doses as high as 5 mg. a day were given.

Subsequently American clinicians have not in the main supported the view that the occasional toxic effects of the synthetic oestrogen are pronounced enough to preclude its use in human therapy. Karnaky[15] has treated in all 189 cases and found nausea in only a few, and suggested that this was eradicated if the tablets were taken after meals. Some patients in this series had doses of 90 to 234 mg. given during three days without any ill results. Since the nausea and vomiting occur as readily after parenteral as after oral administration, there is reason to suppose that the origin of the symptoms is to be found centrally rather than in local irritation. As certain animal experiments had suggested that stilboestrol caused liver damage, Shorr and his colleagues[1] performed liver-function tests on their patients, with, however, inconclusive results. Freed, Rosenbaum, and Soskin,[16] in a recent study of this question, were unable to obtain any evidence for such a toxic action on the liver. They carried out bromsulphalein retention tests on eight menopausal patients before and during stilboestrol therapy, and on the treated women compared with normal women of the same age group. They finally gave 5 mg. stilboestrol daily for three weeks to a man recovering from an acute attack of hepatitis without the slightest evidence that his convalescence had been impeded. Von Haam, Hammel, Rardin, and Schoene[17] have also reported the results of their administration of stilboestrol to 125 patients. They find that, although 42% of their patients developed some untoward symptoms, these could be controlled in all but nine cases by suitable reduction of the dose. These authors carried out very extensive laboratory investigations, but were unable to detect any disturbance of function. Alcohol test meals were performed on some of their patients, and a slight reduction in acid secretion was noted after nauseating doses of stilboestrol.

It is generally agreed that there is considerable individual variation in the tolerance to stilboestrol, some patients feeling nausea with doses as low as 0.5 mg. a day, while others will take 5 or 10 mg. a day without showing any disturbance. In some of the clinical reports there is insufficient indication of the dosage given to the patients, so that one cannot tell whether there has been any attempt to arrive at the minimal effective dose for the individual patients rather than to give some constant dose to each patient purely empirically. Such a report as that of Kurzrok and others,[18] who observed persistent nausea and occasional vomiting in more than one-half of their forty patients, is open to this objection. The experience in France has been somewhat similar to that in the United States in that the first clinical report, that of Varangot,[19] laid heavy stress on the toxic manifestations, while the later reports, such as that of Huet, Comte, and Herschberg,[20] have in general accepted the new substance as a useful therapeutic agent whose toxic effects are slight and can usually be regulated by suitable adjustment of dosage. Huet and his colleagues found that only 10% of forty-six patients developed nausea, and the vomiting which occurred in 3% of cases cleared up rapidly on cessation of treatment.

There seems on the basis of the available evidence little objection to the use of stilboestrol in place of the

natural hormones provided that it is used intelligently. There is no point in giving larger doses than are strictly necessary, and each individual case must be studied to find out what is the minimal dose which will yield the desired result. Most clinical observers seem to be agreed that doses of more than 1 mg. a day are very rarely necessary, and that much lower doses are quite effective in a great many cases. The question of the toxicity of stilboestrol may, however, become a purely academic one if the preliminary data on the newer oestrogenic analogue hexoestrol given by Bishop and his colleagues[21] in the form of a report to the Therapeutic Trials Committee of the Medical Research Council are confirmed. Their findings indicate that the new compound, while not so active weight for weight as stilboestrol, gives rise to nausea and vomiting in a much lower proportion of cases. Its oestrogenic activity is in all respects similar to that of the natural hormones. It is hoped that the controversy on the toxicity of the new compound will be slight; so far no clinical reports have appeared except the one referred to above.

GAUGING CHILDREN'S PHYSICAL FITNESS

All workers in the field of child health are faced with the problem of finding an efficient, economical, and simple method of gauging physical fitness. The Children's Bureau of the United States Department of Labour has recently issued a valuable study on this subject,[22] in which Dr. Rachel M. Jenss and Dr. Susan P. Souther give details of a most interesting piece of work. Put briefly, the method adopted was the observation of over 700 white school children attending the public elementary schools in New Haven, Connecticut, from September, 1934, to May, 1936. These were 365 boys and 348 girls, who were first examined when they were 6 years of age. This examination included a physical examination by a well-trained paediatrician, anthropometric measurements taken by one anthropometrist, and certain social-economic data made at home visits by trained workers. A second examination was made a year later by the same paediatrician and anthropometrist, and in addition the boys and girls were weighed at intervals during the study. When the children reached 7 years of age a comparison was made between what may be termed clinical criteria and four selected indices of body-build, the object being to test the value of such indices in picking out children likely to be physically unfit. The clinical criteria were: clinical judgment of general nutritional status, need of medical and dental care, and an estimate of the child's gain in weight and change in arm-girth over the period of observation. The four indices chosen were: the "Baldwin-Wood index," the "arm-chest-hip index" (developed by the American Child Health Association in 1934), the "nutritional status indices" (based upon a fairly complicated score card), and the "Pryor width-weight tables." Each index requires certain special measurements and in most instances it calls for fairly complicated calculations.

[21] *Lancet*, 1940, 1, 529.

[22] *Methods of Appraising the Physical Fitness of Children*. By Rachel M. Jenss, Sc.D., and Susan P. Souther, M.D. Bureau Publication No. 263. United States Department of Labour. Government Printing Office, Washington. 15 cents.

This study indicates quite clearly that none of these indices is an efficient method of identifying children who, according to the clinical (and continuous) observations, are likely to be physically unfit. The indices proved neither sensitive nor selective, failing to pick out certain boys and girls clearly indicated by one of the clinical criteria to be in need of medical care or nutritional advice and assistance, and, on the other hand, sometimes picking out children passed as physically fit. But even with such clear failure of the indices the clinical aspect of assessment also comes in for criticism. The clinical judgment of the paediatrician who made the examinations was prone to considerable error, in terms both of the variability and of the stability of the judgment. It is certain that some measure of a child's growth, such as periodic weighing, and also some accurate knowledge of the child's dietary habits, are necessary adjuncts to the physical examination. It is to be hoped that this detailed and well-documented American study will clear the air and stop once and for all the wasted energy spent on pursuing any sort of magical index of nutrition. The assessment of physical fitness is probably much more closely related to *function* than to *structure* and not likely to be expressed in numerical form. Although the assessment of the state of nutrition by clinical examination is beset with many difficulties, as has been pointed out on more than one occasion by the leading public health authorities in this country, the American study under review suggests that it offers a better basis than pure anthropometry. Close co-operation between the clinician, the social worker, and the public health expert should make it possible to achieve some satisfactory standards of nutrition.

WAR FINANCE

There is a clearer idea now than was apparent during the last war that a Chancellor of the Exchequer should keep two main purposes in view when framing his proposals: first, that taxes must be collected to meet so far as may be reasonably possible the payments which the Government will have to make: and, second, that an important part is played by the same operation in restricting the purchasing power of the taxpayer and to that extent setting free goods and services for national use. If the private demands of the individual and the public requirements of the Government enter into vigorous competition, prices are forced upwards and we are on the road to that state of inflation which brings hardship to the individual and danger to the State. Sir Kingsley Wood has introduced a new principle into his Budget, which is deliberately aimed at restricting private consumption—namely, that the share of the taxpayer's income (that is, of his purchasing power) which the State can properly withdraw from his control can be increased if there is a reasonable prospect of some portion of it being returned to him in a few years' time. In operation its effect is that, to the extent to which the additional heavy burden of the income tax payable for 1941–2 arises from a reduction in the allowances, "personal," or in respect of "earned income," rather than from an increase in the rate of tax payable, the taxpayer will receive a credit against which he can draw after the war. The reduction in these allowances is such that the maximum amount of "credit" for this year is £65. The extension of the surtax to the field of total incomes between £1,500 and £2,000, which was foreshadowed in last year's Budget, has

not been effected—presumably because taxpayers within that group have been sufficiently hard hit by the rise in the rates of the ordinary income tax. At the other end of the scale the reduction in the exemption limit and in the personal allowances will not only bring in a very large number (possibly two millions) of new taxpayers under contribution, but will also increase sharply the tax to be paid by those who hitherto have contributed only small amounts to the Exchequer. The Chancellor, and indeed the taxpayers concerned as well, are to be congratulated on the fact that last year a system of payment by deduction was successfully launched as regards persons in employment; probably without some such arrangements in force a large proportion of wage-earners, and many of the salaried classes, would now find it extremely difficult to discharge their half-yearly liabilities. The language of war finance speaks in terms of such vast sums that they seem to lose reality; it may suffice here to point out that, as compared with the estimates of the first Budget of last year, the anticipations for both expenditure and revenue were exceeded by about 15%, and that income-tax payers contributed the record sum of £524,000,000 to the total revenue. One sentence from the Chancellor's Budget speech may be quoted as bringing home the extraordinary demands which taxpayers now have to meet: "I may perhaps mention that excluding Excess Profits Tax and Excess Profits Duty, the increases in the taxation imposed since September 30, 1939, alone equal the total produce of all taxes in 1918, the last year of the last war." On the important question of possible inflation Sir Kingsley Wood was reassuring; what he referred to as "the inflationary gap" he regarded as reduced by his proposals and by the activities of the National Savings Movement and other causes to dimensions which, at any rate in the near future, could not be regarded as dangerous. Apart from what might be called the "compulsory savings element" in the income-tax proposals—and the absence of any increase in indirect taxation—the Budget contains nothing novel.

POST-OPERATIVE PERFUSION OF THE BILIARY SYSTEM

The various operative procedures carried out on the gall-bladder and extrahepatic biliary passages do not always give the perfect results that are desired. The factors leading to failure are by no means uniform, and they are by no means always clear. In some cases the failure may be due to the persistence of inflammatory or pre-calculous changes in the intrahepatic or extrahepatic duct system; in some it is due to calculi, debris, or biliary mud in some part of the system; while in others concomitant disease of the pancreas is the cause. But, in general, post-operative sequels are due to the absence of a normal duct system. In recent years various methods have been employed to ensure a better toilet of the biliary ducts, including duodenal drainage, ether lavage of the common duct, and the direct lavage of the biliary ducts post-operatively by means of a syringe attached to the drainage tube. All these procedures are of special value in cases where calculi can be shown by the cholangiogram. Dean Macdonald[1] has recently described a method of continuous perfusion of the biliary passages with the use of an intravenous apparatus. Fluid or antiseptic, which is heated, is introduced from the apparatus through a tube into either the gall-bladder or the common bile duct, percolates through the biliary system, and is returned through a duodenal tube. Relaxation of the sphincter of Oddi is secured by the injection of olive oil or magnesium sulphate, or both, by the inhalation of amyl nitrite, or by the use of nitroglycerin. The effect of the lavage can be determined by examination of the washings returned through the duodenal tube. The method is an ingenious one, and the apparatus includes a choledochometer for measuring the pressure in the duct system and the tone of the sphincter of Oddi. One obvious risk is that small calculi or debris may be forced into the biliary tree and be impacted in the smaller ducts. The author states that "irrigation is a simple office procedure and can be continued by the patient at home." Thus, after the patient has cleaned his teeth and gargled he now washes out his biliary system before setting out on his day's work! Much fuller investigation and trial of the method are necessary before it can be claimed as either safe or really useful.

INJURIES FROM INDELIBLE PENCILS

From time to time there are reports of injuries from indelible pencils. Although the cases recorded are few and far between—generally punctured wounds of the hand or eye—the consequences have now and then involved employers in litigation and considerable costs by way of compensation. In some countries, notably in Germany, special warning notices have been exhibited in offices about the need for immediate medical attention if indelible pencil wounds are sustained. In this country, a few years ago a demand was made for the abolition of the use of copying-ink pencils in Government offices—with what success we do not know. It is not an easy matter to substitute other and less toxic dyestuffs for those commonly used in indelible pencils, but research will probably overcome the difficulties. The most frequently indicted of the dyestuffs employed at present is methyl violet—a member of the triphenylmethane group of dyes, which includes crystal violet and brilliant green—which has recently become popular in the treatment of burns and wounds. The trouble with this valuable group of basic colours is that in high concentration they are powerful protoplasmic poisons. The use of methyl violet for duplicating work and on teleprinter machines is widespread and has not, so far as we know, ever been followed by troublesome effects on the skin of girls engaged in such work except for the inevitable staining, which can readily be removed by simple means. Workers engaged in the manufacture of methyl violet and similar colours are very rarely affected by the dyestuffs. In the grinding and mixing departments they are protected against the possibility of dyestuffs entering the eyes; but, in spite of intense coloration of the tongue and the ready recognition of dyestuffs or their derivatives in the urine, they do not suffer from any toxic symptoms. This immunity is due to the low concentration in which the dyestuff is absorbed. The situation is entirely different when the point of an indelible pencil enters the tissues and rapidly creates a localized zone of intense activity by highly concentrated dyestuffs. Then the filling substances (usually graphite) act as inert foreign bodies. The dyestuff at once begins to dissolve and leads, so long as the concentration is high enough to allow it, to necrosis of the cells with which it comes into contact. In a recent short review of the problem, with a description of two new cases, Mason and Allen[1] state that the skin and its appendages—connective tissue, fat, muscle, cartilage, and bone—may all be affected in regions where the concentration of dye is high. In such conditions the blood vessels become totally necrotic and thrombosed; where the concentration is lower the necrosis may involve only the adventitia, while the media and intima may show round-cell infiltration and proliferation. Secondary

[1] *Ann. Surg.*, 1941, 113, 131.

infection may, according to Ettore, be a factor in producing extensive necrosis of whole digits or phalanges.

The local signs of indelible pencil wounds may be slight At the time of the injury there is some pain for an hour or so, and surrounding oedema. Pain, however, is not a prominent symptom even when the dye has become widely diffused. For a long time a purple exudate may continue to appear from the punctured wound. Incision to remove the "lead" is likely to lead to a refractory ulcer. General symptoms are not common, but according to one author 20% of cases have headache, malaise, anorexia, and general weakness. The general poisonous action of methyl violet is chiefly on the kidneys, but experimental toxicity experiments on mice resulted in congestion of lungs, heart, liver, spleen, in addition, the liver showing capillary haemorrhages and leucocytic infiltration. The treatment of these injuries is immediate complete excision, so that no stained tissue is left behind. The authors state that if this is done the wound can be safely closed with assurance of primary healing. The "lead," they state further, should never be picked out with forceps: this breaks up the foreign body and scatters bits of dye throughout the tissues. In late cases excision of stained tissues is recommended, the wound being left open and allowed to heal by granulation; but this may be impossible if bones, tendons, or other essential tissues are involved. It is important that such injuries should not be tampered with and that immediate surgical assistance should be obtained.

RECOVERY FROM TRICHINIASIS

Trichiniasis is one of the few diseases from which complete restoration to normal can never occur. Although not disabling, as poliomyelitis, for example, often is, its sequels are highly unpleasing to the imagination, since they consist in the harbouring of innumerable living parasites in muscle throughout the body. Unpleasant though this may be, a more important question is whether it has any permanent practical effect. The presence of large numbers of encysted larvae in the muscles might well impair function to some extent, unless some hypertrophy compensated for this; fortunately they produce no inflammatory changes which might otherwise result in a diffuse and crippling fibrosis. Recent sufferers from this disease in England will doubtless be glad to hear that according to Z. Bercovitz[1] there are no permanent sequels at all. He made inquiries about the subsequent history of seventy diagnosed cases, most of whom he actually saw at various stages after recovery from the original acute illness, while the remainder replied to written inquiry. In no case did any disability persist longer than twelve months, and the majority were quite well in much shorter periods than this, usually within one month. The complaint, when it existed, was always of muscular weakness and fatigue, aching, especially on exertion, or tenderness. Although these patients are so soon subjectively normal they have been found to react positively to skin sensitivity and precipitin tests for as long as seven years, and eosinophilia may also persist for long periods. There is, of course, no treatment which will attack the larvae in the muscles, but it is of interest that antibodies to the parasite are developed, and resistance to reinfestation is observed experimentally. The mode of action of these antibodies is peculiar, although it has parallels in other parasitic infestations. J. Oliver González[2] has recently studied it by immersing living *Trichinella* larvae in immune serum, or hyperimmune serum obtained from animals to which successive doses of living larvae had been administered, the effect of which is to enable them to resist doses of a size fatal to normal animals. The action of such serum is to produce a deposit about the oral opening, eventually obstructing it and causing death. When adult worms were placed in such serum, not only was an oral precipitate formed but similar deposits developed around the anal and vulval orifices. Serum from rabbits immunized by injections of an extract of larvae had the same effect on larvae but none on adult worms, from which it appears that there must be some antigenic difference between larvae and adults. These occlusive precipitates are evidently formed by interaction between serum antibody and parasitic secretions.

PATHOLOGY OF CARDIAC PAIN

Some fifteen years ago it became generally accepted that the pathological basis of prolonged anginal pain (with greater or less shock) was thrombosis in a coronary artery leading to cardiac infarction. Further observations have, however, required a modification of this view. It has become evident that acute cardiac infarction is not necessarily precipitated by coronary thrombosis; where widespread narrowing of the coronary tree already exists, infarction may result from further obstruction by haemorrhage into the wall of the artery, or from reduction of coronary flow as a result of some general disturbance—as, for example, an operation. Moreover, coronary thrombosis may often occur without subsequent infarction if there is an adequate anastomotic circulation. Clearly, therefore, to infer the pathology of the different types of anginal pain is not so simple a matter as was formerly thought. An inquiry by H. L. Blumgart, M. J. Schlesinger, and P. M. Zoll[1] throws some light on these problems. A correlation was made in 355 cases between clinical and post-mortem findings. The coronary arteries were injected, radiographed, and dissected according to the method of Schlesinger. Schlesinger had previously shown[2] that in the absence of coronary disease anastomoses between the coronary arteries, though they exist, are not functionally important even in old age. In seventy-two cases one or more main coronary arteries were occluded or considerably narrowed, yet in none were there symptoms of cardiovascular disease. In all these it was possible to demonstrate a good collateral circulation which had compensated for the obstructed vessels; no infarction or fibrosis had occurred, and cardiograms when taken had been normal. In cases with effort angina as the primary symptom and without valve disease or hypertension, coronary sclerosis with complete occlusion of one or more arteries was always found, but in others with congestive failure and angina as an incidental symptom coronary sclerosis was absent. Sometimes anginal pain is prolonged, but is accompanied neither by the other clinical symptoms nor by the cardiographic changes of infarction. Blumgart and his coworkers have in such cases failed to demonstrate infarction post mortem. They suggest that the cause is thrombosis or other means of sudden arterial narrowing, or alternatively some event which greatly increases cardiac work; they use the term "coronary failure" for such attacks, which may, however, be followed by actual infarction and should therefore be treated by complete rest. Finally, in forty-five cases of acute infarction fresh coronary thrombosis or occlusion was absent in twelve; this last group showed old coronary occlusion: there was one exception—a patient with cerebral haemorrhage.

CERTIFICATES BY MEDICAL PRACTITIONERS

G.M.C.'s WARNING NOTICE

At the request of the President of the General Medical Council we print below a Warning Notice as to certificates given by registered medical practitioners in their professional capacity.

1. The organization of the resources of the nation for the combatant service generally, for the supply of munitions, for the mobilization and use of labour, for public assistance, and for pensions, gives rise to a host of occasions on which registered medical practitioners are requested to sign certificates of fitness or unfitness for persons under their care. Such medical certificates, to be valid, must by law be signed by registered medical practitioners only, and this trust on the part of the State is dependent upon the maintenance of a reciprocal skill and good faith on the part of the practitioners.

2. The State is accordingly entitled to assume that a certificate signed by a registered medical practitioner is completely reliable and an honest and proper fulfilment of his obligation.

3. Unverified assertions made by the patient himself, personal opinions as to his fitness or unfitness for various forms of service, or for particular hours of work, and other statements not founded on a careful examination of the patient immediately before a certificate is given, or supported by ascertained facts or conditions, are not proper material to support a certificate signed by a registered medical practitioner as his testimony to facts within his professional knowledge.

4. It has recently been made to appear to the General Medical Council by information and evidence received from competent authorities that in a number of instances there has been a relaxation of the vigilance with which such certificates are being signed.

5. The attention of registered medical practitioners is therefore drawn to the terms of the Warning Notice issued by the General Medical Council with regard to the granting of medical certificates.

The Notice states that

"Registered medical practitioners are in certain cases bound by law to give, or may be from time to time called upon or requested to give, certificates, notifications, reports, and other documents of a kindred character, signed by them in their professional capacity, for subsequent use either in Courts of Justice or for administrative purposes."

The Notice further states that

"Any registered practitioner who shall be shown to have signed or given under his name and authority any such certificate, notification, report, or document of a kindred character, which is untrue, misleading, or improper . . . is liable to have his name erased from the Medical Register."

6. The General Medical Council desires to impress upon practitioners that any such certificate should be granted *only on medical grounds* and from the practitioner's personal knowledge of the health and physical condition of the applicant, as ascertained by him at the time of granting the certificate.

J. B. Gillespie and J. C. T. Rogers (*Arch. Pediat.*, 1940, **57**, 652), who record a personal case of enterogenous duodenal cyst in a boy aged 4½ years, state that in the nine previously reported cases the patients' ages ranged from the newborn period to 15 years. The recognition of the condition was due to early development of obstructive symptoms. In the newborn period a pre-operative diagnosis of pyloric stenosis was not infrequent. Vomiting had been the only constant symptom. Abdominal distension and vague discomfort occasionally occurred in the older patients. An abdominal mass usually in the upper quadrant has been the predominant physical finding. Of the recorded cases, including the authors', eight were treated by operation and four patients made a good recovery.

Local News

ENGLAND AND WALES

Fracture Treatment under Emergency Hospital Scheme

Mr. Ernest Brown, the Minister of Health, attended the annual meeting of the Central Council for the Care of Cripples on March 28. In the stress of war, he said, the "civilian" cripple, whose condition was due to accident or to one of the crippling diseases, must not be forgotten. He relied upon the Central Council, which had already done so much, to see that this vitally important piece of social welfare was not neglected. Turning to the arrangements for the treatment and rehabilitation of the war-injured, Mr. Brown said that under the Emergency Hospital Scheme nineteen special orthopaedic centres had been established in England and Wales, and to these the majority of serious fracture cases, military or civil, would be transferred. At each centre there was a skilled surgical staff—in one centre an American team of orthopaedic surgeons—and a physiotherapy department with trained masseuses. In addition facilities were being developed at each of these hospitals for physical training, games, and occupational therapy. It was realized that nineteen orthopaedic centres was not enough, and the Ministry was at the moment engaged in bringing into the fracture service a number of other hospitals at which there were surgical staffs competent to treat fractures. After the war some of the special hospitals would disappear as the buildings in which they were housed returned to their normal uses, but others would remain as a permanent addition to the country's orthopaedic services. The new hutment hospitals were not a collection of old Army huts, doomed to dilapidation in the course of a few years, but soundly constructed pavilions, built often in brick and concrete, and medical experts had assured him that they made excellent hospitals of which no country need be ashamed. He added that the Ministries of Health, Labour, and Pensions and the Department of Health for Scotland were in close contact over the question of the further rehabilitation of war-injured in the sense of training for a different job if the disability rendered it impossible for the man to resume his old occupation. He hoped that an announcement would shortly be made as to the proposed plans. At the business meeting of the Central Council Dame Agnes Hunt was re-elected President, and the Earl of Dudley and Sir Geoffrey Peto Chairman and Vice-chairman respectively.

Co-ordination of Tuberculosis Services

Regionalization for the tuberculosis services of local authorities was urged in a paper by Dr. G. Lissant Cox, central tuberculosis officer for Lancashire, at a recent meeting of the Joint Tuberculosis Council in London. The main points urged by Dr. Cox were that many local authorities are not large enough to deal adequately with the prevention and treatment of tuberculosis on modern lines, and that some form of combination or regionalization such as already exists in Wales is desirable throughout Great Britain. The county and county borough councils for tuberculosis schemes in England (leaving London out of account) deal with populations ranging from 50,000 to 2,000,000, and although all the authorities are supposed to have schemes similar in efficiency and completeness, this is not in fact the case. There are relatively small counties and boroughs with efficient schemes, but these have been fortunate in having a person of exceptional ability as director or an area with peculiar advantages, and in general it must be said that for so complicated and expensive a work of public health a large authority is in a position to provide a modern scheme more economically than is a small and poor authority. There is already ample legislation to enable local authorities to combine and form general committees or boards for carrying out their statutory duties, but there are only three such combinations in England, those relating to the areas of Staffordshire, Gloucestershire, and Warwickshire respectively, and in those areas the efficiency of combination has been demonstrated. Nine years ago it

Joint Tuberculosis Council recommended that rural areas with a population of 200,000 and urban areas with one of 300,000 could be managed by one whole-time tuberculosis officer with proper assistance, but, of course, the adequacy of areas differs with the aspect of tuberculosis work in view. For isolation, nursing, and some minor surgical treatment a small area may function quite well, whereas it could not function efficiently and economically for more specialized treatment—for example, for non-pulmonary disease, especially of bones and joints, for children and adults, or for major thoracic surgical work. Dr. Cox pointed to examples of regionalization, such as the Welsh National Memorial Association, which conducts the diagnosis and treatment of tuberculosis in Wales and Monmouthshire, and, in more general fields, the scheme of the British Hospitals Association and the Emergency Medical Service, with its twelve regions for Great Britain. These regions, however, do not lend themselves suitably to the purpose of tuberculosis areas, but Dr. Cox urged that some scheme of regionalization, with due regard to the areas of county councils, was highly desirable. Legislation will, of course, be required to enforce a combination of local authorities held to be too small to provide efficient schemes.

Tuberculosis in Shelters

At the same meeting Dr. F. R. G. Heaf presented a memorandum on tuberculosis in shelters. The series of recommendations which it contained, and which were accepted by the council, included the following: that the recommendations of the Horder Committee be carried out as soon as possible; that the provision of special shelter accommodation for the tuberculous in densely populated areas be encouraged; that a special effort be made to examine more frequently contacts of known tuberculosis cases using Anderson shelters; that all children be removed from Anderson shelters used by tuberculous persons; and that no tuberculous person be allowed to use a school shelter. Many of these recommendations, especially those for segregation, can only be applied during periods of comparative quiet, and the point was therefore stressed that action should be taken while it was possible to enforce regulations so that a certain adherence to order and routine may be expected in times of extreme emergency.

Reports of Societies

MASS RADIOGRAPHY AND TUBERCULOSIS

At a recent meeting of the North-Western Tuberculosis Society, held at the Tuberculosis Offices, Manchester, Dr. G. JESSEL, Consultant Tuberculosis Officer, Lancashire County Council, read a paper on "The Role of Mass Radiography in Tuberculosis."

Dr. Jessel said that the diagnosis of early tuberculosis still left much to be desired, despite the marked increase in x-ray facilities in recent years. This was largely inherent in the pathology of the disease. Radiography was only capable of recording the shadows of the moment, which might be characteristic of one or more diseases, and, in the case of tuberculosis, did not necessarily indicate activity. A full clinical investigation of suspicious cases was essential. Mass radiography could be carried out in several ways: fluoroscopy was the cheapest but did not provide a permanent record; miniature screen photography overcame this defect, but its use on a large scale necessitated special apparatus and very careful organization. Miniature mass radiography could provide, under favourable conditions, a rapid method of weeding out those who presented abnormal skiagraphic appearances, and these suspects should be referred to a tuberculosis dispensary for detailed investigation. Persons classed as healthy should be re-examined at intervals, especially in the so-called dangerous industries. Miniature mass radiography of entrants into industry, the Army, etc., had already been tried, and, subject to financial considerations and with certain reservations, might be more generally used as the necessary centres, apparatus, and personnel became available. Definite standards of technique and interpretation would be essential for comparable results of value. The interpretation should be made by teams of experienced radiologists and tuberculosis officers or chest specialists. The examinations should be regarded as part of a general health survey and should not be related in the public mind specifically to tuberculosis. The work should not be carried out at a tuberculosis dispensary, which should remain the centre for detailed examination of suspects.

Dr. A. K. MILLER referred to the economic aspect of this health survey, which would certainly throw workers out of employment, and on that account would probably meet with some opposition. Provision should be made for these unfortunates. Dr. J. CRAW said that of approximately 1,800 lead miners examined by mass radiography, 0.64%, who had previously said they were fit, were found to be tuberculous. Dr. WYNNE-EDWARDS said that experiments he had made so far with a Leica camera had been unsatisfactory owing to distortion. He added that mass radiography of Storm Troopers in Germany had revealed that 8% were tuberculous.

Wartime Problems of Tuberculosis

At the same meeting Dr. D. P. SUTHERLAND, Senior Tuberculosis Officer for the city of Manchester, spoke on "Some Observed Effects of the War to Date." He said that enemy action and E.M.S. requirements had caused a diminution of approximately 10% in the number of beds available. The general evacuation of the towns at the beginning of the war was, on the whole, probably beneficial; children, for example, were dispersed widely and were in many instances removed, at least temporarily, from heavily infected relatives. A later evacuation resulting from war damage to the dwellings of the tuberculous was unfortunately less innocent. There was danger of infection, as the dispossessed tenants were rehoused either in empty houses or in houses already occupied generally by non-tuberculous persons. Concentration and crowding resulted, not only in individual houses but in the immediate vicinity of the bombed town. The fact that the economic circumstances of the general population were now much better than for years might lead to improved nutrition and increased resistance to the results of infection. Rationing might, however, counteract this. The removal of so many cases from hospitals had been associated with an increase in notified cases so far. In a recent broadcast appeal for more nurses for fever and tuberculosis work the Ministry of Health had emphasized the danger of possible increase in the so-called infectious diseases; no less important was the danger from endemic tuberculosis. The difficulties of staffing sanatoria had been steadily increasing for years before the outbreak of war, and competition with Service requirements had since aggravated the position. There was a very large reservoir of trained staff waiting to deal with casualties as yet non-existent; they had nothing to do and were in most cases anxious to be usefully employed. In addition there were thousands of partly trained personnel, many of whom could be, but were unwilling to be, usefully employed in helping with the treatment and care of the tuberculous, who had great need of their services, preferring instead to do alternative work for which there was no call. As a result there was a diminution in treatment and isolation at a time when these things were most necessary.

In the discussion which followed Dr. Sutherland's paper members were unanimous that long hours in crowded munition works and loss of rest due to A.R.P. and Home Guard duties had resulted in the relapse of old quiescent cases. There were many "T.B. minus" cases in the Home Guard.

W. F. Burdick (*J. Pediat.*, 1940, **17**, 654), who reports ten cases in children aged from 3 weeks to 13 years, illustrates the rarity of peptic ulcer in childhood by the fact that out of 21,231 admissions to a children's hospital there were only 8 cases, 6 of which were duodenal and 2 gastric. He advocates a freer use of x rays in children suffering from anorexia, retarded growth, vague abdominal distress, and constipation. By so doing the diagnosis may be made before haemorrhage or perforation occurs.

Correspondence

Bureaucratic Surgery

SIR,—Those who work in the E.M.S. have for some time been receiving examples of medical bureaucracy in the form of instructions to do this or that, but particularly not to do this or that. Many consultants of long and varied experience have responded to these orders with a shrug of the shoulders and a rather unwilling compliance, in the very proper belief that they should always be loyal to the service which they conceived to be of such great importance to the community at this time. One of the latest orders, however, far exceeds any yet issued in its restrictions, for general surgeons are told not only that "all head injuries should be transferred to special neurological units" but that "the term 'head injury' includes scalp wounds in which there is no evidence of bone involvement." I suppose the implication is that the general surgeon is so dull that he may overlook the possibility of injury to bone or brain, while the specialist neurosurgeon is immune from such errors.

We have all of us in our time laughed at the story of the American dentist who had on his visiting card, "Specialist in the extraction of the right upper canine," but our hilarity was evidently misplaced, for it is obvious to anyone who thinks that there are special points about the relation of this tooth to the antrum, and about the dexterity required to remove upper right-sided teeth, which must demand specialized practice that could only be acquired by one willing to leave all the other teeth to similarly specialized treatment. What about dividing the scalp wounds into those of the right and left sides, possibly to be dealt with by right- and left-handed neurosurgeons respectively?

The question of extreme specialization is nevertheless too serious to be dealt with entirely by friendly banter. Having a mental make-up which makes it impossible for me to confine my interests to one small branch of surgery, I thought that my reactions to these many instructions were peculiar and individual, and I should certainly not have ventured to draw attention to the subject had I not found in conversation with colleagues that they were reacting in a like manner, and that a certain feeling of antagonism was arising which might easily affect the efficiency of the service as a whole.

It is, of course, clear that some degree of specialization is necessary, and I am not prepared to say quite where the line of distinction between the general consultant and the specialist should be drawn, but I feel sure that there are undesirable extremes in both directions. It is easy to understand how comforting it must be to those in charge to be able to forestall possible public criticism by the statement that all cases are in the hands of "specialists," but when this means, to take an example, transferring, say, cases of nerve suture from the hands of general surgeons having a big experience of such work in the last war to comparatively junior orthopaedic specialists whose experience is likely to be much less extensive, the apparent advantage to the public surely rests entirely in some hypnotic influence of the term "specialist."

By retaining the services of the staffs of the large voluntary and municipal hospitals the E.M.S. very wisely determined that the more senior members of the service should be men of wide experience and sound judgment (the most important of all surgical attributes for consultant and specialist alike), and it does seem rather derogatory to issue orders to men of such standing; surely the more acceptable method, when it is decided that some mode of treatment has given good results, would be to issue a pamphlet on the subject for the "information" of those handling the cases. On occasions the E.M.S. has adopted this policy, and those in the service have found the information provided very acceptable, but in the case of orders and instructions who is in a position to be his brother's keeper, who decides what methods of treatment are correct, and who demands that no other treatment shall be used? How could the world have received the benefits of the work of Lister, Horsley, Winnett Orr, and a hundred others if this dictatorial atmosphere had cramped their originality?

The question of the State control of medicine is now very much to the fore, and many who have felt an innate repugnance to the idea have recently been asking themselves whether their opposition was not merely unwarranted prejudice, and in consequence, recognizing virtues in such a system, their intransigent attitude has changed to one of tolerance, with possibly a slight feeling of shame at this betrayal of their natural instincts. But if State medicine is to mean bureaucratic control of the actual technical details of treatment and the complete exclusion of individualism of thought and action, it may be that as a profession, and in the true interests of the science and art of medicine, we should think again before accepting it.

Lest it be thought that this letter merely represents crabbing criticism and lack of sympathy with obvious administrative difficulties, I should add that I have been interested in the E.M.S. since long before the war started, and am anxious that the service should be as perfect as possible from the patient's point of view. This, I believe, can only be attained if competent surgeons are still allowed to retain their individuality and to come to their own conclusions as to the merits of any particular form of treatment, since otherwise their interest flags and their duty suffers accordingly.—I am, etc.,

London, W.1, April 6. NORMAN C. LAKE.

Rehabilitation of the Injured

SIR,—In your informative leader on rehabilitation of the injured (April 5, p. 519) reference is made to the Albert Dock Hospital as having a rehabilitation department for one class of occupation only—namely, seamen. This gives a rather erroneous impression. It is true that it is a branch hospital of the Seamen's Hospital Society, but it caters not only for seamen but for all workers in and about the Royal Docks, and these comprise ship repairers, stevedores, railwaymen, factory workers of many grades, millers, gas workers, office workers, and a host of others. Even if seamen alone were taken, each ship can be considered as a self-contained village with a number of different occupations practised by its inhabitants. In addition to the A.B.s there are firemen, greasers, marine engineers, refrigerating engineers, electricians, cooks, and clerks, and this list can be multiplied many times. The rehabilitation department therefore deals with a very wide cross-section of the working community, and the only way it differs from a general hospital is that it is concerned with men and youths only.

In addition to able-bodied seamen, stevedores, and firemen, those attending the department at the present time include ships' officers, clerks, a cook, an engine driver, a van-boy, a painter, some demolition workers, and men from a variety of other occupations, and it is because of the different types of employment to which the men have to be returned that it has been necessary to evolve a form of rehabilitation work which would cover all. Mr. E. A. Nicoll in his absorbingly interesting article (p. 502) emphasizes throughout the fact that he is dealing with a specialized type of work in the colliery district. His methods are designed to rehabilitate the men in particularly arduous labour, often undertaken in cramped conditions.

It would be very interesting to hear from him what the men's reactions are to the chart of their weekly progress. In the better type, I can believe that the chart would act as a stimulus to further endeavour, but in others I should imagine that by focusing the attention on the disability it is apt to induce a state of introspection and consequent inhibition of effort. My own efforts have always been aimed at distracting the patient's attention from the injured part, although in selected cases benefit is produced by deliberately training the damaged limb or back.—I am, etc.,

London, W.1, April 9. H. ERNEST GRIFFITHS.

Treatment of Burns

SIR,—The Dickson Wright method of treating varicose ulcers with tightly applied elastic adhesive bandages, and the closed plaster method of Winnett Orr of treating deep bone sepsis introduced a new conception into the treatment of localized septic wounds. The success of these methods of treatment

a decrease . . .

. . . due to increase

in demand and subsequent reduction in manufacturing costs enables us to produce DAGENAN—M & B 693 more economically. Continuing our normal policy, the saving thus afforded is being passed on to the consumer by way of a lower price—the third reduction since DAGENAN—M & B 693 was introduced. The revised prices are as follows to take effect on and after the 14th April, 1941 :—

★ DAGENAN—M & B 693 ★

The perfect cigarette with the exclusive filter tip

The filter tip will keep you fit

IT IS NOW MORE THAN EVER NECESSARY TO EMPTY YOUR PACKET AT THE TIME OF PURCHASE AND LEAVE IT WITH YOUR TOBACCONIST

is due to certain underlying principles common to both. They can be stated briefly as follows: (1) Elimination of tissue tension. (2) The bactericidal effect of wound discharges retained in intimate contact with the wound. (3) The "cushion" effect of a fluid dressing on the wound. (4) "Protection" effect produced by local immobilization and infrequent change of dressings. (5) Beneficial psychological effect produced by freedom from pain and from the mentally disturbing effects of frequent painful dressings, anaesthesia, baths, or irrigations.

For the last twelve years I have employed these principles in general practice in the treatment of wounds, clean or septic, of abrasions of the skin surface, of boils and carbuncles, and also of burns and scalds. Here let it be quite clearly understood that I am dealing only with small areas of burns and scalds, so that the question of treatment by tanning methods to prevent secondary shock does not arise. The treatment now being discussed applies only to local burns and scalds, where the considerations that arise are: (1) the formation of a clean granulating wound that later can be allowed to heal by epithelization or by skin grafting; and (2) the comfort and convenience of patient, doctor, and nursing staff.

The leading article in the *Journal* of March 29 (p. 484) calls attention to the importance of the control of sepsis in burns. In the same issue (p. 469) Dr. J. M. Robson and Mr. A. B. Wallace advocate the use of glycerin–sulphonamide for its antiseptic properties. Others advocate the use of flavine incorporated in a tannic acid jelly, while others press the claims of gentian violet and other aniline dyes. I would here like to suggest an extended trial of the occlusive method of treating burns, using as a bactericidal agent that which I believe to be the best of them all—the seropurulent discharge of the wound itself. I see no logical reason why sepsis from a varicose ulcer, an infected bone injury, or from a boil or carbuncle should be treated differently from sepsis arising in a burn or scald. Within the limited scope afforded by general practice I have treated them on the same lines as I have treated sepsis elsewhere, and have never had cause to regret what I believe to be a 100% run of successful results. Excluding tetanus and gas gangrene, I believe the principles set out above apply to sepsis whatever the nature of the invading organism.

The occlusive dressing technique is simple. Vesicles, when present, are ruptured, but the overlying epidermis is not removed. The burned areas are swabbed with dry cotton-wool and gross contamination is removed. The surrounding healthy skin is shaved and cleaned with aether. meth. A piece of white lint is covered with a layer of any bland ointment (I use ung. resorcin. c. amylo) and placed over the wound so that its edges reach just beyond the margin of the wound. This is covered by strips of elastic adhesive bandage applied on the stretch two layers deep, the outer overlapping the inner layer, or the bandage may be wound in spiral fashion round a limb. This dressing is left *in situ* for seven to twenty-one days, being reapplied after recleaning the wound and its surrounding skin as before.

In this fashion a second-degree burn may be completely healed in three to six weeks, with perhaps only one or two changes of dressings. In the case of a third-degree burn a healthy granulating wound will be found ready for skin graft after two to three weeks. Apart from satisfactorily dealing with sepsis and the comfort of the patient, this occlusive type of dressing has the following advantages: (1) It is not bulky and it "stays put"; even when the feet and legs are involved in second-degree burns the patient is able to walk about in comfort after a few days. (2) There is a drastic economy in time to doctor, nursing staff, and patient. (3) There is a drastic economy in the use of dressing material. (4) The patient can usually return to useful work two or three weeks before the complete healing of the wound, providing he can manage to avoid subjecting the dressing to contact with water.—I am, etc.,

Derby, March 31. E. C. DAWSON.

SIR,—As an ignoramus on the subject I have followed with interest the oscillations of the experts who advise on the treatment of burns. Tannic acid, acclaimed as a life-saver a few years ago, seems to be going out of favour. Fomentations, specifically condemned in a Ministerial pamphlet some months ago, has received a recent word of commendation (Mowlem, *Proc. roy. Soc. Med.*, February, 1941, p. 221).

I would ask one question and make one comment. What became of the treatment by paraffin wax which had a considerable vogue in the last war? Those interested in the subject will find laudatory articles in both volumes of the *Journal* for 1917. With cessation of hostilities the method seems to have faded into oblivion.

The donor area from which Thiersch grafts have been taken has suffered many things at the hands of many surgeons. One shudders when one reads of sepsis developing under tannic acid treatment when experience has shown that perfect healing will occur under a sterile dressing of gauze and wool, left in position until the scab separates in the course of two or three weeks. Similar treatment will give good results in the case of a second-degree burn if the blisters are intact so that they can be cleansed and punctured, not cut away, with aseptic precautions.—I am, etc.,

Northampton, April 6. C. C. HOLMAN.

SIR,—I would advocate the use of paraffin No. 7 in the treatment of burns at aid posts. It gave good results in the last war, and I have found nothing better for domestic burns. It can be easily stored, kept clean, and has some antiseptic value. The melting of the wax should give reasonable asepsis. As it is applied warm, shock is minimized: it is a soothing application. Perhaps a safe percentage of novocain could be added. Anyone can learn how to apply it.

The teaching in E.M.S./Gen./343 will be confusing to first-aiders. They have been told to avoid carron oil and greasy applications, yet here is vaseline recommended; and the tubes of tannic acid jelly with which first-aid parties are provided are to be discarded. Whatever be the best hospital treatment, a practical and authoritative statement on first aid seems called for. How is vaseline to be sterilized and kept sterile in an aid post? Vaseline, like carron oil, can too easily become a menacing mess.—I am, etc.,

Gourock, April 5. GEORGE ADAM, M.D.

Tuberculosis in Wartime

SIR,—In the annotation on tuberculosis in wartime (March 22, p. 445) the commentator draws attention to the unsatisfactory features of institutional treatment of tuberculosis, and remarks that even before the war only an insignificant number of sputum-positive patients were discharged as quiescent. Surely this latter statement is a slip of the pen, for it is difficult to see how any patient with a positive sputum, however good his general condition and no matter how free from toxic signs he may be, can be regarded otherwise than as an active case of pulmonary tuberculosis.

In the review by Rusby and Heaf quoted by your commentator attention is again drawn to the large numbers of sputum-positive patients outside institutions who constitute "a vast pool of infection in the country." With wartime conditions prevailing it is inevitable that in the coming years we shall be faced with a grave increase in the incidence of the disease, and that the need for early diagnosis and effective and thorough institutional treatment will be even greater than before the war. Are we to regard these sputum-positive cases mingling with the general population at present as evidence of the failure of our anti-tuberculosis work and as a reflection on the efficiency of our scheme of treatment? Rather let us say that our hospitals and sanatoria have done their best with the clinical material provided and with the resources at their command.

If we look to the future, however, we must be driven to the conclusion that if we are to deal adequately with the cases of the post-war era a reorganization of our scheme will be necessary. Early diagnosis will remain the foundation stone of our edifice, and there will be little doubt among tuberculosis workers that mass radiography will provide the solution. Given early diagnosis, prompt use of collapse therapy will shorten the period of institutional treatment and should greatly diminish the number of sputum-positive cases, thus gradually eliminating our "pool of infection."

Is our present tuberculosis scheme adequate, as it stands, to deal with this problem, and, if not, what reorganization will be necessary? In certain areas the scheme administered by the local authority is admirable, in other areas most definitely not so admirable, and in our coming onslaught on

the disease uniformity will be essential. For this some form of central control, such as a National Tuberculosis Board, should be considered. Given our central board, we can work our scheme on a regional basis, with each region equipped with a central hospital where facilities for all forms of collapse therapy are available, and with a specialist staff employed on a full-time basis. From our hospital we pass to the regional sanatoria, which are intended for sanatoria and not, as at present, for sanatoria-cum-hospitals-cum-homes for incurables. Included in the scheme would be a rehabilitation centre and colony, for it is idle to suppose that in our "brave new world" we shall see nothing but early unilateral cases who one and all respond to a pneumothorax. In our shadow scheme we must also consider one other vital point—the education of the public—for without this our plans will most surely fail. The organization for this is in being in the National Association for the Prevention of Tuberculosis, which could be incorporated in the general scheme.

The cost of such a scheme as has been outlined would certainly be great, but, taking a long view, the results should more than repay the expenditure, and perhaps we might yet see the day when our sanatoria would come to occupy the same position as our small-pox hospitals do now.—I am, etc.,

Tor-na-dee, Murtle, March 26. R. Y. KEERS, M.D.

Collecting Casualties in Invasion: A Scheme for Kent

SIR,—The medical service of the Home Guard is at the moment in so fluid and formative a condition that even a few weeks' experience may be of interest to your readers. For some six weeks I have been the senior medical officer of this service in Kent, and as such responsible for its organization and character. Not until quite recently have I seen any Army Orders or other instructions which concerned themselves with this particular medical service, and I have good reason to believe that even now the authorities are far from anxious to lay down hard-and-fast rules which experience might prove to create more difficulties than they solved.

My first discovery was that there was practically no resemblance between the duties of a regimental medical officer and those of a Home Guard battalion medical officer. Such resemblance as there was concerned only their sanitary and training duties. When it came to dealing with casualties the resemblance abruptly ceased. There can be no question of establishing a single regimental aid post for a country battalion of the Home Guard, since it may be spread over a hundred square miles and have small detachments on guard at almost as many separate road junctions and other defence points within the area. The same difficulty has faced the medical officers of mechanized regiments, in which vehicles may at any time become very closely analogous to a Home Guard defence point. I do not know how the regimental problem is being solved, but it is evident that the Home Guard battalion has at least one advantage—that is, the area in which it will sustain casualties is limited by counties and not by continents. This fact is of no small importance.

Those who have followed the argument so far will probably say, "Well, where is the difficulty? There are air-raid wardens everywhere, who will ring up Control and have an ambulance sent out to take your casualties to hospital without requiring the services of a battalion medical officer." Those who still believe that this simple mechanism will surely be available during invasion are dangerous optimists. Whether invasion comes from the sea or the air, or both, it must be the first aim of the enemy to disorganize means of communication and so prevent the arrival of reinforcements. This must surely mean attacks of great strength on the neighbouring towns (including hospitals), and upon all roads, railways, and bridges. "In great strength" means something that we have not yet experienced in this country, but Rotterdam knows what it meant a year ago, and we should do well to learn its lesson. That lesson is clear enough. In areas affected by invasion we must arrange to disperse our casualties, or leave them dispersed, during the actual fighting, partly because we shall not be able to do anything else, and partly because it would be sheer murder to seek to aggregate them in vulnerable centres such as town hospitals and first-aid posts. I have found that those in the best position to visualize the possibilities of invasion heartily approve of the dispersion of casualties.

It did not take one very long to reach this conclusion, and the next step was to arrange for the reasonable care of casualties until it should be both possible and wise to send them to hospital. This could only be done by enlisting the assistance of doctors who could influence householders in their own districts. About forty Home Guard medical officers have now been enrolled in Kent. Most of them are battalion M.O.s, but some are responsible for groups of four to eight battalions, and others are associated with companies or even platoons. These officers and I have aimed at setting up casualty collecting posts throughout the county at such intervals from each other that it will not be necessary to carry any casualty more than one mile. No elaborate provision is or can be contemplated, but we hope to ensure that the injured shall have a roof over their heads, rest, warmth, simple cooking, and such skilled care as may be possible. We have a form which we hand to householders. The response has been extremely encouraging, and there are already a great number of casualty collecting posts in various parts of the county. In many instances it has been possible to arrange that a retired doctor or a dentist with a medical qualification shall take the responsibility of two or three such posts. In others the local doctor (who is often also the battalion M.O. or a member of the Home Guard) will look after them as best he may. A trained nurse is available for others, and there are many helpers with various degrees of training who are more than willing to assist in time of need.

Although the Home Guard medical officers are bringing these casualty collecting posts into being, their duties do not usually include attendance at them in emergency. Many of these doctors have their duty posts—for example, F.A.P.s, E.M.S. hospitals, and so on. The Home Guard medical service, as it exists in Kent, is in fact an administrative and not a treatment service. It is in this fact that it differs so strangely from the R.A.M.C. In this manner, within a very short period, we have gone far to ensure that no casualty, Home Guard or military or civil, shall be left neglected by the roadside or in some unsuitable cottage until the fighting is finished and road traffic resumed.

I should like to discuss the adaptation of this plan to towns, and also a hundred and one other points which have arisen, but many of these are more suitable for conference than print, and your space is too valuable for further presumption on my part.—I am, etc.,

GORDON WARD,
Senior Medical Officer, Kent Zone, Home Guard.

Sevenoaks, April 7.

Mobile Unit in Action

SIR,—Allow me to endorse Dr. F. J. Henley's final dictum in his letter on this subject (March 22, p. 458): "Use these units more and they will save more lives," but to whom does he or do we address this request? He asks whose specific responsibility it is in Southwark to send for the unit. I expect it is the same in Southwark as in this borough and all other boroughs: Controls call out the unit on the advice of the incident officer, if there happens to be one present, but more often on the advice of stretcher-bearers, or rescue party, or even a part-time warden. Surely these expensive units are worth more consideration.

We are told we are on the eve of invasion, when casualties may approximate to the figure which we were originally taught to expect; may we as medical officers of mobile units not plan so that we may be of more use? Local A.R.P. committees may not have used mobile units as much as they should, and perhaps rightly too, because except in a few cases the incidents have not been large enough to absorb all their functions, which were laid down very early by the Ministry as follows: (1) for trapped cases, (2) for urgent cases requiring treatment *before removal*, (3) as casualty clearing stations, (4) for improvising a hospital should hospitals and first-aid posts be destroyed. Except perhaps in the case of (1) and (2) most units (according to correspondents) do not appear to have been utilized. There is no reason, however, why they should not be prepared to act in these capacities, and A.R.P.

committees would be well advised to co-operate with medical officers of mobile units and so enable them to be ready for future action.

I suggest that the criticisms and suggestions made in the *Journal* by experienced M.O.s of mobile units might be met by some such scheme as the following:

(1) At each express message where casualties are reported the M.O., a sister, and the incident doctor's deputy (as suggested by Dr. Henley) should go out with an ambulance arranged as a resuscitation unit, as indicated by Dr Peter Cardew (January 18, p. 100). If the casualties are few and slight the deputy through the warden gets in touch with Control and asks for the next incident. If the incident is of some magnitude, he calls out the unit, mobile van, etc., and he then works in conjunction with rescue and stretcher parties as Dr. Henley suggests: (*a*) sees that no casualty is carelessly handled; (*b*) sees that shock treatment is started and maintained as soon as the patient is at all accessible; (*c*) keeps account of the number of casualties rescued and number to be rescued; (*d*) acts as casualty clearing officer, directing ambulances to the various hospitals and first-aid posts and not all to the nearest hospital; and (*e*) affixes red, blue, and white labels to casualties according to severity of wounds, priority of treatment, and destination.

(2) Personnel of the mobile unit should be interchangeable with those of other units so that the staff of each unit can be easily augmented.

(3) The personnel of mobile units should be trained in the team work of improvising a hospital.

I should be glad to hear from M.O.s of mobile units so that a meeting may be convened and this scheme or a similar one embodying their experiences can be presented, perhaps through the agency of the British Medical Association, to the proper authority.—I am, etc.,

J. F. MACKIE.

London, S.E.22, March 27. M.O., Camberwell Mobile Unit.

A First-aid Timetable

SIR,—In pursuance of the idea and burden of your leading article of two weeks ago about the tendency to over-elaboration of first-aid work, I have a suggestion for instructors. It is that they set their description of any and every case, real or otherwise, against a time schedule—that is, they indicate what could and should be done within the periods of, say, half a minute, one minute, five, ten, twenty, and so forth. Within such a place as a first-aid post the staff might, through transport difficulties, etc., find themselves in the position of nurses, and would then have to do such work as the recording of temperature, pulse, and respiration, and repeat at intervals spread perhaps over longer periods still.

Thus: 1. *Immediate, Half-minute.*—Remove from electric contact; place in a posture favourable to respiration: close an open pneumothorax. (The first thing, of course, would be to observe whether there is unequivocal evidence of death.)

2. *One Minute.*—Haemorrhage: direct or digital pressure; throw a covering over to protect against chilling; tourniquet, if needed; examine for fractures if there is time, and apply, so far as possible, postural treatment for them, including the clavicle.

3. *Five Minutes.*—Splints to forearm and ankle; for worse fractures, place on a stretcher and remove the patient without splinting, though secured to the stretcher as firmly as time will allow; cover up burns if not already done.

4. *Ten Minutes.*—Count pulse and respiration rates in all cases of head, thorax, and abdominal injury (even though there be no external wound); examine for further wounds; put splints on major fractures; prop up in Fowler's position if necessary; dress burns.

5. *Twenty Minutes.*—If washing facilities are available and lotion, the wound, after first cleansing the surrounding skin, may be uncovered and inspected for foreign bodies and so forth; look out for and record signs of cerebral compression (specified in detail), internal haemorrhage, and peritonism; treat for shock and (controlled) haemorrhage by rectal injection of really warm 1/2% saline; hot bottles between the thighs and to arm-pits; examine badly crushed limbs for evidence of vitality (colour, temperature, and pulse to be felt); and be prepared on medical instruction to apply a tourniquet if the state of the limb is so bad as to prejudice the well-being of the injured man.

The above may be found suggestive: it could obviously be elaborated and improved on.—I am, etc.,

W. REGINALD WILSON.

April 6. M.O., First-aid Post, Doncaster.

Radiological Diagnosis of Peptic Ulcer

SIR,—In base hospitals and elsewhere all over the country numbers of H.M. Forces suffering from gastric symptoms are being examined radiologically. This provides a suitable opportunity to assess the value of the radiologist in this field and also to define his responsibilities.

Enlightened criticism has recently been directed against a tendency on the part of physicians and surgeons too readily to accept a radiological report. Dr. Charles Newman at a meeting this week reminded us that a "coin in the slot" attitude towards a radiological diagnosis can be most pernicious. As a radiologist I heartily endorse this. This attitude, however, is part of a vicious circle. Too little responsibility has in the past been placed upon the individual radiologist. A patient is sent for examination, a report is received, and the physician notes what "they" in the x-ray department have to say. Sometimes, happily infrequently, a picture or two of the stomach is considered sufficient. Seldom, however, even when the report is particularly nebulous, is the radiologist charged with the case and cross-examined as to the true significance of his findings. As a result it is little wonder that reports often take the form of a brief stereotyped formula, which irritates the physician and may convey to him little useful information.

The duodenal ulcer is a case in point: the search for this lesion requires the most precise and meticulous observation, yielding evidence of almost every stage of inflammatory change and of the sequelae of healing. A precise interpretation, or at least a statement of the probabilities when the findings are abnormal, should be demanded of every radiologist who undertakes a barium meal. In demanding it, the physician on his part will gain a better appreciation of the scope of radiology, of its ability to give more valuable information than much that is given now, and also of its limitations; while a reasonable share of the responsibility would be a healthy stimulus, welcomed by all radiologists who are prepared to stand or fall by the value of their work.—I am, etc.,

London, W.1, March 29. A. M. RACKOW.

Dyspepsia in the Services

SIR,—As a sidelight on the prevalence of dyspepsia in the Services—and among the civil population from whom they are recruited—I had a conversation some time ago with a member of a firm of retail chemists who own about a dozen shops in an industrial area. He asked me to guess the amount of alkaline powder sold by his firm each month. In putting the figure at a couple of hundredweight I imagined I should be well outside the mark. To my surprise he said that the amount averaged about half a ton per month.

It would be interesting to know to what extent digestive troubles are *post hoc* or *propter hoc* if this is any indication of its consumption over the whole country.—I am, etc.,

Brookwood, Surrey, April 5. H. M. STANLEY TURNER.

Medical Planning Commission

SIR,—It appears to me that the solution of this problem is comparatively simple. Two main essentials stand out: (1) the planning should be started as soon as possible: (2) the younger members of the profession must have a say in the matter, as they are the ones most concerned. Let the present commission get to work now and commit their proposals to paper. After the war the present commission should resign and a new commission be elected on which the youth of the profession would be fairly represented. This new commission could then review the findings of the original commission in a comparatively short time, as most of the spade-work would have been done.—I am, etc.,

Newbury, April 8. H. WARBURTON LEWIS.

SIR,—I am desired to notify you of the following resolution which was passed at a recent meeting of this committee after discussion had taken place on the objects and constitution of the Medical Planning Commission: "This committee dissociates itself, in advance, from any findings of the Medical Planning Commission as at present constituted."

For your information I am also desired to say that in framing the above resolution this committee had in mind the following points: (1) No scheme for a medical service which does not secure the agreeable acceptance of the general practitioners is likely to succeed. (2) The general practitioners have the power to enforce their will if they are united in purpose, know what they want, and shout loudly enough for it. (3) The way to oppression and depletion is waiting to see what will happen and doing nothing. Some aggressive policy must be adopted and energetically proclaimed. (4) Our chief potential enemies are those of our own household, the principal menaces being: (*a*) the growing insufferable powers of medical officers of health; (*b*) the envious hungry glances of consultants towards the National Health Insurance Funds. (5) We must urge on the Minister of Health that the general powers of co-option which are conferred upon local authorities by the Local Government Act, 1929, and which enable them to appoint representatives of the medical profession on the Public Health Committees, should be made compulsory instead of permissive, as at present, and that the local Medical and Panel Committees should have the right to nominate such representatives.

To sum up, there are two cardinal principles for which we must fight: the maintenance of a living wage and freedom from interference; in other words, liberty.—I am, etc.,

G. GILBERT GENGE, Hon. Secretary,
April 10. Croydon Medical and Panel Committee.

Calcium Requirements

SIR,—Dr. I. Harris and Messrs. Ireland and James (January 11, p. 49) have made a careful review of calcium metabolism and the many unsolved problems connected therewith, and consider that there is no evidence of calcium deficiency in the country. I have lately perused a group of modern papers on the subject, mostly from the U.S.A., kindly supplied me by the librarian of the B.M.A., and find that though there is plenty to say, conclusions are as dogmatic as they are contradictory. This seems odd considering the amount of chalk and lime in the world, especially in Southern England, and that rickets has been called "the English disease," and that the triumph of vitamin D has been one of the marked advances in preventive treatment during the last two decades. The recent correspondence in the *B.M.J.* shows difference of opinion on the subject. Certainly the clinical evidence of calcium deficiency is difficult to come by notwithstanding Sir John Orr's statement that the vast majority of the population suffer from this insufficiency.

I can only approach the subject as a clinician: estimations of serum calcium are not possible for me, and my patients are comparatively few. I come from Thanet, near the North Downs, where the condition of our water pipes, unless the water is softened, is enough to prove that there is plenty of calcium if the body metabolism is ready to take it up. However, I have decamped to Devonshire for obvious (not calcium poisoning) reasons, and here there is very little calcium in the water. The amount in the North Down waters averages about 20 parts per 100,000. In the surface moorland water supply of North Devon it is only about 4, half of which is calcium carbonate. (The analyses I have looked up in Thresh, Beale, and Suckling's *Water Supplies*.)

In the area where I am now practising the water comes from Exmoor. The local hotels and lodgings are full of schools, mothers with small children, and delicate people, mostly from areas where calcium has been abundant. Now the symptoms of calcium deficiency are said to be: poor circulation, chilblains, depressed heart action; fatigue and nervous irritability, even tetany; catarrh and asthmatic symptoms; and, presumably, bone softening when the deficiency has gone on long enough to deplete the calcium reserve stored in the bone cells; dental caries, etc. All through this winter of wet rough weather severe long-lasting colds with bronchial catarrh and spasm have been very frequent among these people. There has been asthma, but not acute cases. Fatigue is obvious, perhaps to be accounted for by steep-hill walking, and also by "summer time" in winter. The children have lost weight in spite of cod-liver oil, etc.

I have seen no tetany, facial spasm, or bone softening. On the other hand, the local children are free from rickets; the dentists do not complain of overwork and their reports are satisfactory. I do not know what local physical signs to look for indicating parathyroid underaction or atrophy. Yet it seemed to me only wise to put the patients on wholesale lime-water, which they make for themselves at home with slaked lime and tap-water, and I am bound to say that on the whole it has been a great success. The colds and catarrh at all events have cleared up more quickly and the children are putting on weight. I should much like to know whether lime-water is an easily absorbable sort of calcium: if not, my observations are merely wishful-thinking. In some cases where I have thought the deficiency was urgent I have ordered calcium lactate for fourteen days, but I have not injected calcium gluconate, which I understand is the best method of introducing rapidly the missing element.

If I am correct in my treatment and observations the administration of calcium should be of value to those attending evacuated persons in Devonshire, especially the children.

I am not at all clear how calcium gets into vegetables, eggs, meat, etc., except through water. The original calcium here in North Devonshire has been metamorphosed into quartzite, etc.—I speak under correction—and is insoluble; there is none on Exmoor, where analysis shows that the water is very soft. On the other hand, how is it that the local children have no rickets? They do not eat much, if any, fish, unlike the children of the Hebridean islands with their herring diet; and their teeth are not in trouble to any marked extent. It may be that the body has an amazing capacity for taking up what it wants from a very meagre supply. Perhaps we over-regard the quantities in our dietaries and do not investigate sufficiently the more important problems of assimilation after digestion, thinking too much of our treatment and not enough of how Nature works, reacts, and defends herself.—I am, etc.,

Mortehoe, April 9. H. M. RAVEN.

Vitamin B_1 in Diphtheria

SIR,—Dr. Duncan Leys's criticism (March 29, p. 495) of our paper on vitamin B_1 in diphtheria (March 8, p. 359), the value of which can be assessed by the fact that he apparently has not taken the elementary precaution of carefully reading what he purports to criticize, affords us an opportunity of amplifying our previous statements. Naturally in an article presented for publication it is impossible to give very full particulars of the cases used in the experiment, and we trusted that this necessary pruning would not detract from the value of the article for the average intelligent reader.

We would first of all like to point out that Dr. Leys's statement that "none of their control cases appear to have had heart failure at all" is incorrect, since control case No. 2 is definitely mentioned by us as suffering from heart failure. Moreover, control case No. 10 developed a bradycardia on the twenty-fifth day, a fact which apparently had no significance for Dr. Leys, thus indicating that he is probably unaware of the importance of bradycardia in diphtheria. Secondly, his statements on tests Nos. 9 and 12 show that he has missed the whole point, as these cases were used to try out the curative effect rather than the prophylactic action of vitamin B_1; as there was nothing unusual in the rate of recovery there was nothing to remark about it. He states that we do not mention how long after treatment death occurred in test No. 7. The article shows that despite fourteen days' intensive treatment with the vitamin the patient died. As a matter of fact the patient developed gallop rhythm on the thirty-third day of the disease and died on the forty-first day.

We feel that Dr. Leys is trying to draw a red herring across our path by introducing other toxic states. May we remind him that our article was not on other toxic states but on the value of vitamin B_1 in diphtheria. Consequently there is no need for us to express our views on the value of the vitamin in these other conditions. We suggest that his own two cases

prove nothing: he does not even mention that they were cases of diphtheria: they could, from his letter, be due to other toxic conditions: the dosage of the vitamin is not given: he did not mention whether the vitamin was given before the appearance of the symptoms or after—if before the symptoms this shows that the complications appeared despite the vitamin B,: if after the appearance of symptoms, he is doing what he blames us for doing in some of our cases. There is no proof that the recoveries were not due to the other treatment: his numbers are too small and he had no controls.

It is a fact that if a therapeutic agent is really good it quickly and universally establishes itself, but despite the number of years that vitamin B, has been tried for complications of diphtheria there is no sign that this stage has been reached.—We are, etc.,

Antiseptic Snuffs

SIR,—I read with much interest the article by Drs. M. E. Delafield, Edith Straker, and Prof. W. W. C. Topley (February 1, p. 145) on a proposed method of applying chemotherapy in nasal infections. The use of snuffs might be very useful but the formulae suggested are dangerous. I would refer the authors to a report by I. H. Erb, pathologist to the Hospital for Sick Children in Toronto, on lycopodium granulomata. It will be found in *Surgery, Gynecology and Obstetrics* 1935, **60**, 40. Lycopodium was used as a dusting powder for rubber gloves in that hospital until several cases of granulomata, at least one of which caused intestinal obstruction and another involved the maxillary antrum, were discovered. If the small amount of lycopodium spores derived from a surgeon's gloves could cause tumour formation in an antrum, what might be expected from a snuff each dose of which would carry many times the quantity accidentally applied in the operation? It would not be unreasonable to fear lycopodium granulomata in the lung.

Nor is magnesium carbonate much better. A series of cases cited by McCormick and Ramsay in the *Journal of the American Medical Association*, **116**, No. 9, March, 1941, showed serious reactions in the peritoneal cavity due to the adherence of talc (magnesium silicate) on surgeons' gloves. The idea of the use of snuffs is good and the bacteriological studies are convincing, but I respectfully suggest that the vehicle used fulfil the ancient admonition "primam nolle nocere."—I am, etc.,

Toronto, March 8. MALCOLM H. V. CAMERON.

Chemotherapy in Acute Otitis Media

SIR,—Although fully conscious of the honour of Mr. Lionel Colledge's interest (March 22, p. 455) in my article on chemotherapy and conservatism in acute suppurative otitis media (March 15, p. 399) and appreciative of his kindly if somewhat sombre warnings, I have more than a faint suspicion that he wrote with his tongue in his cheek. Were it not so, to call conscientious clinical investigation, however modest, "looking for trouble" would appear to be ungenerous, and reminds one of the execrations showered on the heads of a band of recalcitrant "trouble-seekers" who dared to do as Hunter advised Jenner, "Don't think—try"—to name only a few: Jenner, Lister, Simpson, and Mackenzie.

Perusal of the case-sheet reports and of the discussion makes it clear as to the offending organism, but absence of "streptococcal" in the conclusions may justify the reminder of the pneumococcus and the *Staphylococcus aureus*. With the recent great advance in our knowledge of the action of sulphanilamide derivatives the reminder is not material. It would be interesting to know whether it was Mr. Colledge's innate kindliness which led him to omit mention of the tubercle bacillus, which may be the primary cause of suppurative otitis and which definitely gives no response to this therapy.

As to bacteriological investigation, I agree that it should be done when and where possible, in the absence of or in confirmation of clinical findings, but that ideal is seldom attainable in a rural district miles from the nearest laboratory where the bacteriologist is not always available. Further, the time factor is all-important: just as with clinical diphtheria and cerebrospinal fever one dare not wait for isolation of the Klebs-Löffler bacillus and the meningococcus, so with acute suppurative otitis media the application of chemotherapy should not depend on the existence of a discharge from a drum ruptured either spontaneously or by incision.

I note that in the case quoted of the nurse with acute pneumococcal suppurative otitis media, "when it appeared as though a mastoid operation could scarcely be avoided," the condition responded satisfactorily to suitable chemotherapy without surgical measures. I could ask for no more complete confirmation of my thesis. With full laboratory facilities at his immediate disposal it surprises me that no typing of the pneumococcus was done with a view to more appropriate treatment—by chemotherapy appropriate to the special strain. In the second case quoted no mention is made as to close supervision, repeated examination, and the multiple safeguards upon which must depend the decision as to whether conservative treatment may be proceeded with safely. Any humiliating experience which I may meet should be no worse than that which the aural surgeon meets (but may not recognize as such) almost daily in his awkward necessity to carry out paracentesis in the same drum repeatedly or to follow one mastoidectomy with a second in the same ear.

The initial anxiety, which was associated with only the first two cases and which soon became one of pleasurable anticipation, was a natural and healthy reaction, and was no more than one would expect in Mr. Colledge if he were trying out a new technique, say, in paracentesis or any sculptural effort.

The trifling analogy is, I feel, entirely facetious, but I must confess to having exposed myself to the alluring if demoralizing influence of Ireland on a few short visits. As to my abandoning my so-called defiance of established indications for incision of the tympanic membrane, the complete non-existence of these is proved by a recent discussion on the "Causes of Failure in the Treatment of Acute Otitis Media" recorded in the Section of Otology (of which Mr. Colledge is president) in the *Proceedings of the Royal Society of Medicine* (February, 1941, p. 225).—I am, etc.,

Malvern Link, April 3. J. B. JESSIMAN, M.D.

Convulsions under Anaesthesia

SIR,—Dr. H. A. Logan (March 29, p. 480) makes no allusion to hyperpyrexia as a possible cause in his interesting account of a case of so-called ether convulsions. No mention is made of the temperature at the time of operation or for twelve hours after, and so presumably it was not taken, or not for some hours after the convulsions had ceased. In view of the prominence given to hyperpyrexia as a cause of ether convulsions in the discussions in these columns recently it seems a pity that this was not done. It was suggested, I believe by Mr. Hamilton Bailey, that such a measure is impracticable, and so it probably would be at the height of severe convulsions. However, if the temperature be taken as soon as the convulsions abate, or, if necessary, when the operation is concluded, the observation should still be significant as the body is unlikely to have cooled unduly.

A brief description of a case of anaesthetic convulsions which I observed recently may be of interest. Male aged 18, retrocaecal appendicitis. Temperature just before operation 102° F. No abnormality detected in the chest on routine examination. Gas, oxygen, and ether anaesthesia induced with Boyle's apparatus. Generalized symmetrical jerkings of the limbs and trunk started some ten minutes after the peritoneum was opened and when the patient was in full surgical anaesthesia. The theatre was very warm and the patient extensively covered with mackintoshes, towels, and blankets. Most of these were removed and as much of the patient exposed as was consistent with the maintenance of surgical asepsis. Evipan was prepared for injection, but as the surgeon was not grossly inconvenienced and was able to complete the operation rapidly it was not deemed necessary to give it.

At first the convulsions increased and were very violent for a minute or so, then gradually died down and finally ceased

some twenty minutes after their onset and after ether administration had been stopped and the excessive coverings removed. At the end of the operation the rectal temperature was 104.5° F., and it is probable that it was higher before measures were taken to "cool off" the patient. Further progress was uneventful.

It is not inconceivable that the high temperature in cases such as this might be the result rather than the cause of the convulsions. Other observers may perhaps have the opportunity of obtaining a temperature reading at the onset of the convulsions should their severity or the nature of the operation not prohibit this. Nevertheless, a reading of the temperature immediately the circumstances allow is of value in that it may help to show whether or not hyperpyrexia is always associated with these convulsions—an observation apparently not yet fully established.—I am, etc.,

South Shields, March 29. J. B. KINMONTH.

SIR,—Dr. Logan gives a very helpful account of a typical case of what is known as "ether convulsions." I have been interested in this condition for about twenty years. As Dr. Logan suggests, no real cause has yet been found, all manner of theories have been put forward, and almost every kind of treatment has been tried or recommended. There are, however, two points which emerge, and which I think are accepted as constant. First, the condition is nearly always connected with an attack of appendicitis in a young person. Secondly, the convulsions never come on before the anaesthetic has been in progress about twenty minutes.

The only satisfactory treatment of this condition is preventive. Side-track the ether as soon as induction is over and carry on with nitrous oxide and oxygen; whichever way we look at the condition, ether is toxic and nitrous oxide is not. I am somewhat suspicious of atropine, which seems to have been used in nearly all the cases reported; I use less as time goes on. A second convulsion, as Dr. Logan mentioned, is not very uncommon.—I am, etc.,

J. B. H. HOLROYD, M.R.C.S., L.R.C.P., D.A.,
March 29. Anaesthetist, Sheffield Royal Infirmary.

Cyclical Mucosal Ulceration

SIR,—I notice a rather unnecessarily sarcastic letter from Dr. M. H. Pappworth (April 12, p. 573) which did *not* reply to my letter and question. The point is that Dr. Pappworth has not answered my query, and one must assume that blood examinations were not made, and if they were made that an eosinophil count was not done. One must therefore assume that this publication was made without full investigation, which, I suggest, should be done before decrying friendly criticism.—I am, etc.,

Liverpool, April 14. J. BERNSTIEN.

Outbreak of Gastro-enteritis

SIR,—The outbreak of acute gastro-enteritis described by Lieut.-Colonel A. H. D. Smith and Captain D. J. Davies (April 12, p. 554) resembles a similar epidemic that occurred in this county in the same period of 1940. The characteristics were: (1) abruptness of onset; (2) rapidity with which successive members of families were affected; (3) the short course of the disease. Owing to this short duration and absence of unpleasant sequels the disease appeared to be unworthy of the title "gastric influenza." One was inclined to accept it as an act of God or of the King's enemies, and to await the next *crise de guerre*.—I am, etc.,

Sherborne, Dorset, April 13. J. WHITTINGDALE, F.R.C.S.

Nitrous Oxide for Dental Anaesthesia

SIR,—I have administered "straight N_2O" in some hundreds of dental cases during the last thirty-three years. I am driven to the conclusion that the war product differs considerably in its effects (and possibly in its method of production) from pre-war nitrous oxide. Briefly, I have noted a prolonged period necessary for induction, shallow and slow respiration, no stertor, an analgesia rather than an anaesthesia, and, worst of all, a marked delay in recovery often with syncopal symptoms. My technique has not varied; different apparatuses have been tried. Incidentally all apparatus has been checked by N_2O experts, who can offer no explanation. Other local doctors have experienced similar effects. It would be interesting to know whether any of your readers can account for the phenomena and suggest a remedy.—I am, etc.,

Petts Wood, April 4. B. RICHARDSON BILLINGS.

Albinism

SIR,—The cases of albinism reported by Dr. Edward Christianson under "Clinical Memoranda" (April 12, p. 556) will be of interest to all those who may concern themselves with the condition. This note is merely to suggest that the monograph on albinism by Pearson, Nettleship, and Usher from the Department of Applied Statistics, University College, London, should have been included in the bibliography. Therein will be found a number of cases described by me among dark-skinned natives of Africa; others are the subject of an article in *Biometrika*, 1913, **9**, Nos. 3 and 4, 333.—I am, etc.,

London, W.1, April 12. HUGH S. STANNUS.

Malignant Measles?

SIR,—With reference to Dr. Audrey Baker's letter (March 8, p. 380) dealing with a so-called case of malignant measles, I am in agreement with Dr. Geoffrey Goodwin's suggestion (March 22, p. 462) that this was a case of suprarenal haemorrhage, or, in full, a fulminating meningococcal septicaemia or Waterhouse-Friderichsen syndrome. A good description of a typical case is given by Dr. James F. Hughes in the *Journal* of September 14, 1940 (p. 353).

In a series of 300 cases of cerebrospinal fever admitted to the City Isolation Hospital, Cardiff, during 1940 I saw at least six cases of this nature. The outstanding features were the sudden onset, multiple petechiae and often ecchymoses, and a rapid pulse of low tension imperceptible in some cases, meningitic signs being absent and the cerebrospinal fluid clear in the early stages. In one patient the medical superintendent, Dr. Emrys Harris, was able to demonstrate numerous meningococci in a stained smear of the centrifuged deposit of a haemolysed specimen of blood.

There is profound toxaemia, and the haemorrhages into the suprarenal glands produce a very marked lowering effect on the blood pressure. Unless these are immediately combated with the administration of intravenous saline, together with sodium sulphapyridine soluble, and a suprarenal cortical extract, the prognosis is hopeless and death may occur within a few hours. Three patients, with an imperceptible pulse on admission to hospital, made a good recovery when treated on the lines indicated.—I am, etc.,

D. TREVOR THOMAS,
Swansea, April 1. Medical Officer of Health.

Crush Injuries

SIR,—Dr. S. W. Fisher, H.M. Medical Inspector of Mines (April 5, p. 534), asks for information on crushing injuries in mines. The Medical Research Council has also been seeking such information for many weeks but so far without success. Prof. H. A. Harris, however, hints in his letter (March 29, p. 491) that he is familiar with this type of injury in the coalfield. It would be helpful if he could document his experience for the sake of the common weal.

In the study of a syndrome such as this facts must be marshalled as carefully and completely, and in these days as rapidly, as possible. No useful purpose can be served by loose thought based on inaccurate and incomplete reading of the data followed by vague ideas about colostrum, crush injuries, and uric acid infarcts. On the other hand, any available *facts* concerning the clinical course of crushing injuries, or the development of renal failure in other types of injury, would be welcomed by those of us who are concerned with the provision of accurate and helpful information.—I am, etc.,

J. McMICHAEL,
Secretary to the M.R.C. Subcommittee on Traumatic Oedema.

British Postgraduate Medical School,
W.12, April 14.

Discission of Secondary Cataract

SIR,—Most ophthalmologists at some time or other have found difficulty in dealing with an after-cataract by means of a needle or a Ziegler's knife. The difficulty is in getting a *point d'appui*, and the fibrous membrane often simply moves in front of the instrument and is neither torn nor cut. Mydricaine is well known as a powerful mydriatic which does its work efficiently without raising the tension, but it is not sufficiently recognized that if 2% solution of cocain hyd. is instilled, and after an interval of three or four minutes a subconjunctival injection of 5 minims of No 2 mydricaine (Meorfields) is given, the discission can be done easily. The membrane becomes taut and the operation then presents little difficulty.—I am, etc.,

Wanstead, E.11, March 28. FRANCIS E. PRESTON

Pulmonary Oedema

SIR,—With reference to the annotation (March 22, p. 447) on Luisada's view of the reflex origin of acute pulmonary oedema, may I point out that the idea is by no means a new one. It was put forward, for example, by S. Wassermann in the *Ztschr. Arch. inn. Med.*, 1933. The earliest reference I can find is nearly thirty years old. In the *Lancet* of May 27, 1911, A. E. Carver gives an admirable and detailed description of two cases, and concludes that certain features observed in these cases "raise the question whether reflex vagus stimulation was not a factor in determining the onset of the attacks, and this element of nervous influence would account for the beneficial effects of treatment with morphine and chloroform, an experience which coincides with that of other observers in similar cases."—I am, etc.,

Paignton, March 31. ATHELSTANE HILL.

Medico-Legal

MURDER OR ACCIDENT?

The medico-legal evidence decided the question of guilt or innocence in a recent murder trial.* A woman had been found lying on her back in a bedroom. There had been a small blood-stained area on the carpet, and the body had various bruises and abrasions on the scalp, forehead, left eye, arms, and legs. Pressure had been applied to the tissues of the neck; some of the abrasions looked as though they might have been caused by finger nails. Her upper denture had two teeth broken recently, probably by a blow in an upward direction. Her husband was put on trial for her murder.

Prof. John Glaister gave the opinion that she had died of cardiac arrest during asphyxia. The character and distribution of certain of the injuries, particularly on the neck and arm, he considered to be inconsistent with self-infliction or accident. Although, if the injuries were taken individually, many of them were quite consistent with accident, yet if they were taken collectively he could not account for them in that way. Cross-examined, he said it was highly improbable that the bruises on her arms were caused by a clumsy attempt to lift her from the floor on which she was lying face downwards. She had taken a large quantity of alcohol not long before her death—nearly a whole bottle of whisky. She was probably very drunk, and if she fell might lie in a helpless and comatose condition. He agreed that in that condition she might be more liable to sudden cardiac collapse than if she had been sober. In answer to the judge, Lord Wark, he said he thought the pressure to the neck had been applied by human hands and could quite easily have been applied from the front with the right hand. Her condition, if she was unused to alcohol, would have tended to coma rather than to violence, but she might have needed restraint to prevent her from injuring herself or someone else. He agreed that her injuries might have been caused by being caught momentarily by a person who was endeavouring to restrain her or fend her off. Dr. A. P. Husband said that the fracture of the artificial teeth was consistent with violence, and he did not agree that they had been broken by striking the edge of a fender, for then they would have been more shattered. He also thought it highly improbable that they had been broken by a fall on a hard surface.

After the case for the Crown had been completed, Mr. G. R. Thomson, K.C., the Advocate-Depute, reduced the accusation to one of culpable homicide. Prof. Sydney Smith, giving evidence for the defence, developed the possibility that the woman might have died of alcohol. Regurgitation might have passed from the stomach to the windpipe and caused suffocation, which if death resulted would leave symptoms of asphyxia. The bruising could have been produced by a fall, and the damage to the denture could have been caused by the woman falling on her face. He had conceived the idea that she had been very drunk, unable to stand and falling about. If there had been another person in the house, that person was probably in the same condition. It was hardly possible that the wife would go on drinking by herself in the presence of the husband without being stopped, unless they were both drinking. She might have fallen on the fender so that her face and head, and possibly her heart, struck the kerb. Another thing to consider was that she had fallen forward on her face, and her husband might have tried to lift her by the shoulder and pull her up. Very considerable force was required to lift a limp body, and the scratches might have been caused by the attempt. The jury were absent only seven minutes before they brought in a unanimous verdict of Not Guilty.

* *Glasgow Herald*, Saturday, Feb. 22, 28.

The Services

HONORARY PHYSICIAN TO THE KING

Major-General J. A. Manifold, D.S.O., late R.A.M.C., has been appointed Honorary Physician to the King, vice Major-General J. W. L. Scott, C.B., D.S.O.

HONORARY SURGEONS TO THE KING

Major-General O. W. McSheehy, D.S.O., O.B.E., late R.A.M.C., and Colonel (temporary Brigadier) C. M. Finny, O.B.E., late R.A.M.C., have been appointed Honorary Surgeons to the King, vice Major-General F. D. G. Howell, C.B., D.S.O., M.C., and Colonel B. Biggar, respectively.

NAVAL MEDICAL COMPASSIONATE FUND

A meeting of the subscribers to the Naval Medical Compassionate Fund will be held on April 30, at 3.15 p.m., at the Medical Department of the Navy, 64, St. James's Street, S.W.1, to elect six directors of the Fund.

MENTION IN DISPATCHES

Surgeon Commander William Flynn, R.N., has been mentioned in dispatches for courage and devotion to duty when H.M.S. *Liverpool* was damaged during an attack by enemy torpedo-carrying aircraft.

CASUALTIES IN THE MEDICAL SERVICES

Colonel EDWARD MEREDYTH MIDDLETON, O.B.E., late R.A.M.C., was killed by enemy action in March, aged 60. He was the eldest son of the Rev. F. E. Middleton, late Rector of Hayesford, Norfolk, was born on October 10, 1880, and was educated at Toronto University, where he graduated M.B. in 1905, and at St. Thomas's Hospital, taking the M.R.C.S., L.R.C.P. in 1906. Entering the R.A.M.C. as lieutenant in 1907, he became colonel in 1935, and retired in 1937, when he joined the Reserve of Officers, in which he was serving as Assistant Director of Medical Services, Western Command, at the time of his death. He was on his way to a hospital when he was killed by a bomb. He served in the war of 1914-18 and was mentioned in dispatches in 1916.

ROYAL ARMY MEDICAL CORPS

Lieut. JOHN INGLEBY WILSON is posted as "Died" in an Army Casualty List published on April 7. He was 33 years of age and qualified M.R.C.S., L.R.C.P. in 1933. Before the war he was in practice at Knaresborough, Yorkshire.

Obituary

SIR GEORGE TURNER, K.B.E., C.B., F.R.C.S.,

Consulting Surgeon to St. George's Hospital

Sir George Turner, consulting surgeon to St. George's Hospital and, during the last war, consultant to the Navy with the rank of surgeon rear-admiral, died at Adelaide Crescent, Hove, on April 7, aged 85. His elder brother, the late Edward Beadon Turner, was for many years a leading figure in the central work of the British Medical Association, and the clock facing the inner courtyard of B.M.A. House commemorates his long service on the Council and chairmanship of the Representative Body. Both brothers were educated at Uppingham School during Edward Thring's headmastership, and went on to St. George's Hospital, and they were devoted sons of these two foundations; they were also fine athletes and played rugby football for England in the early international matches.

George Robertson Turner was born at Chigwell, Essex, in 1855; his ancestors were Devonshire people, and three of his uncles were doctors. Leaving Uppingham in 1872 he had a distinguished career at St. George's, winning an exhibition, a scholarship, and several prizes. He qualified in 1877, and after acting as house-surgeon and demonstrator of anatomy obtained the F.R.C.S. in 1880. He was then appointed surgical registrar at St. George's, and in 1887 assistant surgeon, by which time he had become a member of the visiting staff of the Seamen's Hospital at Greenwich, and he served the Dreadnought for eighteen years. In 1914, on the outbreak of war, he was posted temporary Surgeon Rear-Admiral, and in that capacity worked at the R.N. hospitals at Chatham and Plymouth, and as surgical consultant to the Admiralty. Part of his time when he was nominally at Chatham was occupied by a voyage to Malta to bring back some 700 wounded from Gallipoli. For his services in the war he was created C.B. in 1917 and K.B.E. two years later. He retired from the active staff of St. George's in 1918. In earlier years he had been examiner in anatomy for the English Royal Colleges and office-bearer in the Medical Society of London. He wrote articles for Heath's *Dictionary of Surgery* and for Latham and English's *System of Treatment*.

Sir George Turner had a warm heart and a breezy manner and prided himself on his outspokenness; he wrote, "I have dared to live my life without an over-regard for what people thought and said of me." He often remarked that the Turners were very conservative, and the word "democracy" made little appeal to him. His service with the Navy in wartime gave him great joy, for he loved the company of sailors. It was said by a shrewd judge of men, Sir Henry Burdett, with whom he had many passages of arms at the Dreadnought Hospital, "Turner knows what he wants and usually gets it." In 1931 he published his *Unorthodox Reminiscences*. This discursive book is a mine of good stories about men in various walks of life, particularly in the world of sport and racing, and the last chapter relates many interesting experiences that came his way when he wore naval uniform. Lady Turner died in 1926. Of their five children one son was killed in the last war, and one of the three daughters married Mr. G. A. Ewart, surgeon to St. George's. In retirement at Hove Sir George maintained his characteristic vigour of mind, and up to a short time ago was notably alert and active for a man of his advanced age.

W. MITCHELL SMITH, M.D.

By the death of William Mitchell Smith at the age of 68 on March 20 North Staffordshire mourns the loss of one of its foremost citizens and the crippled child a true and kindly friend.

A native of Aberdeenshire, Mitchell Smith graduated at Aberdeen University, for which he retained always a great pride and affection. He was never happier or more interesting and entertaining than when speaking of his beloved Scotland, of his boyhood days and his ever-cherished parents, of his life among the crofters, and of his old teachers and the profound influence they had on his future professional career, particularly, perhaps, Sir Alexander Ogston, whose portrait hung in his consulting rooms. Towards the end of last century he settled in the picturesque village of Tean, about ten miles from Stoke-on-Trent, where he soon built up a very large country practice. Alert, enterprising, and level-headed, he kept himself fully abreast of the progress in medicine and was always ready to adopt new methods if, after careful study, he considered that such treatment would prove of benefit to his patients, with whom he had great influence, and in their turn they looked upon him as a friend and wise counsellor.

Mitchell Smith was naturally a lover of children, and he was blessed with the power of obtaining the confidence, affection, and understanding of young people; he was keenly interested in those diseases common to children, and after he had firmly established his practice it was his custom to attend various children's clinics, particularly those of Still and Batten. In the early days of the last war he became associated with me in the care of crippled children at Hanchurch, a home originated by Millicent, Duchess of Sutherland, and Mr. Sydney Malkin, the father of a well-known orthopaedic surgeon, and the late Dean of Carlisle, who was then Rector of Stoke; the work increased to such an extent that further accommodation had to be found, and a small house was rented in the city for the treatment of out-patients. About this time I handed over to him, and later a further move became necessary as the amount of work was growing, and Smith decided to give up his practice and to devote his whole time to work among cripples—a very courageous step to a man who was then over 40 years of age. Eventually, with the help of many kind and interested friends, some old stables were converted into a Cripples' Home, which flourished, and still further extensions were added, until eventually an entirely new hospital was built, one of the foundation stones of which was laid by Sir Joseph Cooke, a native of North Staffordshire, and at that time Premier of Australia. In 1930 the Prince of Wales opened a new block, and in the following year a very fine open-air ward was opened by the Duchess of Portland.

In order to gain further and special knowledge of orthopaedic surgery, Smith became a resident at the old Baschurch Hospital, where he had the good fortune to come under the guidance of Dame Agnes Hunt, the late Sir Robert Jones, and the late Naughton Dunn, all of whom became his lifelong friends and who on many occasions conducted clinics at the hospital, when Sir Robert would bring with him distinguished orthopaedic surgeons from home and abroad. These clinics were greatly appreciated by the local members of the profession and were always well attended, and it was an inspiration to study Mitchell Smith on these occasions, overcome as he was with pride and joy when his results were praised and criticized by the great master Sir Robert Jones. The continued success of this hospital is due to the determination, keenness, and foresight of Smith, for it was by his own perseverance and unbounded energy that so wonderful a result followed upon such small and humble beginnings.

Mitchell Smith's one thought in life was the crippled child, their education while inmates of the hospital, and their training to become useful members of the community in the workshops attached to the hospital. He established also clinics for the treatment of cripples in various towns in North Staffordshire, which he visited regularly, and they proved most popular and successful; he was also closely associated with the children's clinics organized by the city and county authorities. Later, when the hospital decided to admit adult patients suffering from deformities, he showed the same enthusiasm and skill

In dealing with fractures Smith had unbounded patience and he was a master in the art of manipulation, reserving operative treatment until other methods had failed, though he was a sound surgeon, especially when dealing with deformities of the feet.

A brusque manner hid a very kindly heart and we, including numbers of patients, especially children, will ever retain happy memories of the man, with a real appreciation of the work he has performed, of a loyal friend who reached a high position by his determination, by dint of hard work and by his constant belief in the best and only the best, and finally he will ever be remembered as the man who first raised the treatment of crippledom in North Staffordshire to the high position it now occupies.

ERIC E. YOUNG

FREDERICK JOHN McCANN, M.D., F.R.C.S.

Dr. F. J. McCann, consulting surgeon to the Samaritan Free Hospital for Women, Marylebone Road, died on March 28. He was born in Edinburgh and educated at the University there, qualifying in medicine in 1888. After serving as demonstrator of anatomy at Edinburgh he came south, and held in turn the positions of resident medical officer to the Belgrave Hospital for Children and Queen Charlotte's Lying-in Hospital, house-surgeon to the Children's Hospital, Great Ormond Street, and senior house-surgeon to the West London Hospital. Dr. McCann built up a considerable reputation as a gynaecologist, and presently acquired a large consulting practice in Wimpole Street. In addition to his work at the Samaritan he was consulting gynaecologist to the West End Hospital for Diseases of the Nervous System and to a number of other hospitals in and around London.

He became a member of the Royal College of Physicians of London in 1892, took the M.D. of Edinburgh, with honours, in 1897, and the F.R.C.S.Eng. in 1901, and he was a Fellow of the British (now the Royal) College of Obstetricians and Gynaecologists from its foundation. He was a man who cultivated the international outlook. His medical education was completed in Berlin and Dresden, and he made close acquaintance with the medical schools of Paris, Leipzig, Vienna, Munich, Budapest, and Lisbon. When the fifteenth International Medical Congress was held at Lisbon in 1906 he was honorary president of the Section of Obstetrics and Gynaecology. He was also a member of the Société Internationale de Chirurgie and vice-president of the Ligue Internationale pour la Vie et la Famille. He was an excellent public speaker, with deliberation in his choice of words, and in the old days of the polyclinic in Chenies Street a highly popular lecturer there. He was also prominent in a number of medical societies, and had occupied the chair both of the Chelsea Clinical Society and of the West London Medico-Chirurgical Society. He was author of several works on his specialty, the chief of which was *The Treatment of Common Female Ailments*, which went through several editions; also *Cancer of the Womb: Symptoms, Diagnosis, Prognosis, and Treatment*; and he contributed the articles on gynaecology to several medical encyclopaedias.

In his dignified appearance and manner, his air of deference and old-world detachment, McCann recalled an earlier age in medicine, and given a wig and a gold-headed cane he would have fitted into the picture of eighteenth century physicians. But he was far from indifferent to modern trends and methods, and his kindly disposition evoked affection among a wide circle of friends and juniors.

JOHN SMYTH MACDONALD, F.R.S.

The death took place at Bridge of Allan, Stirlingshire, on March 29 of John Smyth Macdonald, F.R.S., Emeritus Professor of Physiology at Liverpool University.

Prof. Macdonald was born in Dublin in 1867, but his father's home was at Chester, and there, at King's School, he received his early education, going on to Emmanuel College, Cambridge, and to Liverpool University, where, in 1891, he was Holt Fellow in Physiology. It was a circumstance of great pride to him that, twenty-three years later, he should be called back to his old department as Holt Professor of Physiology. He was also, in 1899–1901, a research scholar of the British Medical Association. The other Association scholars of those same years were the future professors G. Elliot Smith and J. W. H. Eyre. After holding teaching posts in the physiological laboratories at Liverpool, Dundee (St. Andrews University), and Sheffield, he became in 1903 Professor of Physiology at Sheffield University, and this chair he held for eleven years. Then came what he regarded as the greatest honour of his life, his appointment to Liverpool, where he succeeded his great and revered master Sir Charles Sherrington, who had been Professor of Physiology there for almost two decades. His tenure of the chair was almost as long as Sherrington's, and on his retirement under the age limit in 1932 he was made professor emeritus.

Several contributions were made by Macdonald to the *Proceedings* of the Royal Society, of which he became a Fellow in 1917, and to the *Quarterly Journal of Experimental Physiology*. At the Annual Meeting of the British Medical Association at Sheffield in 1908 he was honorary secretary of the Section of Physiology, and when the Association met in Liverpool in 1912 he was president of the same Section. His short presidential address on that occasion was chiefly devoted to demonstrating an antagonism between serum and blood corpuscles. He was an original thinker with an unusual way of putting the facts of physiology before his students. For example, thirty years ago he was likening the muscles to energy pumps which, by their proprioceptive mechanism, retransmitted impulses to the central nervous system. He also suggested that the role of oxygen in the central nervous system might be that of a scavenger. He rejected the opinion which regarded the nerve fibre as an insulated path and the cell body as a battery: in its place he held the view that the nerve might be regarded as equivalent to a series of batteries.

In his later years Prof. Macdonald had lived in quiet retirement in Lincolnshire and in Scotland. He had married a Scottish lady, Miss Stewart of Stornoway, who survives him.

DR. DAVID DIAMOND, M.R.C.P., D.P.H., deputy medical officer of health for the city of Kingston-upon-Hull, has been killed by enemy action. He was born in London and received his early education in South Africa and his medical education in London at St. Bartholomew's Hospital, qualifying L.R.C.P., M.R.C.S. in 1923, and, having chosen public health as his career, he proceeded to the D.P.H. in 1931. After gaining experience in Holborn and the Port of London he was appointed assistant medical officer of health under the Hull and Goole Port Health Authority in 1931. In 1934 he became senior assistant medical officer of health in charge of the Tuberculosis Department, which post he held until his appointment as deputy medical officer of health for the city of Hull on January 1, 1939. He obtained the M.R.C.P. in 1937. The M.O.H. for Hull sends the following tribute: "We, who were privileged to be his colleagues in the Hull Health Department, mourn the loss of an able colleague and a brave man. The death while on A.R.P. duty of Dr. David Diamond came as a great shock to us all. He was appointed to the staff of the department in 1931. His ability secured for him rapid promotion and he became deputy medical officer of health. His wide knowledge of men and affairs stood him in good stead in his approach to the many and varied public health problems of this City and Port. Since the war he had been closely associated with the organization and administration of the A.R.P. casualty services, and the end came while he was engaged in controlling the operations of the service in the creation of which he had played so important a part. He will long be remembered as an able physician, untiring in his efforts to ameliorate the lot of his less fortunate citizens, and as a promising public health administrator. Our deepest sympathy is extended to his widow and two young daughters in their sad bereavement." Dr. Diamond joined the British

Medical Association twelve years ago, and at the time of his death was a member of the Council of the East Yorkshire Branch.

Dr. JOHN TAYLOR died at Dunfermline House, Elgin, after a few days' illness, on March 31. He had been a member of the British Medical Association for nearly fifty years and was a past-president of the Northern Counties of Scotland Branch. His professional training was at the University of Aberdeen and the School of the Royal College of Surgeons of Edinburgh. He graduated M.B., C.M.Aberd. in 1886 and proceeded M.D. in 1891. After qualifying Dr. Taylor returned to his native town, Elgin, and built up a large general practice. He held many local appointments in and around Elgin and was consulting surgeon to the Fleming Hospital at Aberlour. During the greater part of his career he had close associations with Dr. Gray's Hospital, of which he was for many years visiting medical officer. On retiring from the active staff of the hospital in 1938 the managers placed on record their high appreciation of the services he had given to that institution, and made him an honorary consulting surgeon. He was also a Justice of the Peace for Morayshire.

Dr. THOMAS HARTIGAN, who died on April 2, studied medicine in Dublin and Newcastle and graduated M.B., B.S. of Durham University in 1893, proceeding M.D. in 1907. He practised in London for many years, at Gloucester Terrace, W. "F. N. R." writes: The news of Dr. Hartigan's death will be received with very real grief by his friends, colleagues, and patients. With his quiet reserve, he was not an easy man to get to know, but behind this lay a fund of endearing qualities, not the least of which was his dry and never-failing sense of humour. He was the epitome of what a doctor ought to be: the kind physician with a power of imparting confidence and a sense of trust, given only to those possessed of real ability and a great human understanding. Neither rash nor too conservative in outlook in his dealings with patients, he held to the single objective of what was the very best which could be done for each one; added to this was a real kindness of heart, such as is rarely met. I saw him quite recently, and his preparations for the inevitable had been made with that calm consideration for others so characteristic of all his utterances and actions. Those of us who were honoured by Thomas Hartigan's friendship will count ourselves fortunate, grieve at his departure, and look back upon his example.

The following well-known foreign medical men have died: Dr. JAN SCHOEMAKER of The Hague, twice president of the Dutch Medical Association and President in 1935 of the International Surgical Congress at Cairo, aged 69; and Dr. CHARLES LAUBRY, professor of cardiology in the Paris faculty of medicine, aged 69. Both were Honorary Fellows of the Royal Society of Medicine.

Universities and Colleges

ROYAL COLLEGE OF PHYSICIANS OF LONDON

At a meeting of the Royal College of Physicians of London on April 7 Sir Charles Wilson was elected President.

The Licence of the College was granted to Mohamed Abdul Hafeez of Osmania University and West London Hospital.

Diplomas in Ophthalmic Medicine and Surgery were granted, jointly with the Royal College of Surgeons of England, to the three candidates whose names were printed in the *Journal* of March 22 (p. 465); as were the names of the nineteen successful candidates for the Diploma in Tropical Medicine and Hygiene.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

SURGERY.—E. W. Crews, C. Farès, S. Wetherell.
MEDICINE.—M. M. El Garrahy.
FORENSIC MEDICINE.—M. M. El Garrahy.
MIDWIFERY.—P. L. McN. Armstrong.

The diploma of the Society has been granted to E. M. Crews, M. M. El Garrahy, and S. Wetherell.

Medical Notes in Parliament

Mr. Ernest Brown on April 10 received a deputation on the Medicine Stamp Duty. The members of the deputation were Captain Elliston, Sir Francis Fremantle, Mr. Keeling, Sir Robert Bird, and Lord Wolmer. All were in favour of the retention of the tax. Mr. Brown is to bring in a Bill proposing its abolition. A further deputation is projected to Sir Kingsley Wood.

Insurance Practice of Casualty Service Doctors

Mr. ERNEST BROWN, on April 1, told Mr. Groves that an insurance practitioner was required to make all necessary arrangements for securing the treatment of his insured patients where prevented from giving such treatment himself by urgency of other professional duties or other reasonable cause. If neither the practitioner nor his deputy was available any other insurance practitioner could be required to give it. A fee was payable to the last-mentioned practitioner, subject to the claim being passed by the panel committee. The fee was recoverable from the patient's own practitioner unless the panel committee was satisfied that there was reasonable cause for not summoning him.

In reply to another question by Mr. Groves, the Minister said that in a number of areas a rota of doctors for duty at first-aid posts, medical aid posts in public shelters, and food and rest centres had been arranged. Similar arrangements for providing medical attention for insured persons was a matter for agreement between the panel committee and insurance committee of each area concerned, and detailed information was not available.

Registration of Alien Doctors

Mr. BROWN explained on April 2 that the Medical Practitioners (Temporary Registration) Order, 1941, and the Defence Regulation under which it was made provided for the registration of doctors of certain alien nationalities not possessing British medical qualifications, if they were employed or had been selected for employment in an approved hospital or other institution or service not involving domiciliary practice. He said it was not intended to fix a maximum number of doctors who should have the benefit of the Order. Up to date twenty-eight doctors of enemy nationality had been selected for employment in accordance with the Order.

Accommodation for Fracture Treatment

Answering Mr. Magnay, Mr. BROWN on April 3 said he proposed to provide for fracture cases occurring among industrial workers so far as possible under the Emergency Hospital Scheme. The hospital accommodation available included a large number of beds in hospitals and orthopaedic centres which were, or would shortly be, specially equipped for dealing with fractures and for giving the most modern forms of physical therapy and occupational therapy. For war casualties, both military and civil, these facilities were welded together into a comprehensive organization, supervised by the consultants in orthopaedic surgery employed by the Ministry of Health and the Department of Health for Scotland, so that the patients could be sent to the hospitals best suited for dealing with their injuries and, if necessary, transferred from one to another. The treatment of casualties was and must remain the primary purpose of the Emergency Hospital Scheme, but, to secure the fullest possible use of the organization, the Government had decided that in so far as there were vacant beds not likely to be required for the treatment of war casualties, they should be made available for fracture cases occurring among other classes of the civil population whose early return to work was of special importance to the national cause. These included the injury was sustained in the course of their duties or by manual workers engaged in munition work (including building and ship repairing), building and civil engineering, mining, agriculture, fishing, public utility undertakings, shipping and transport, would be eligible for treatment in these

centres under the emergency scheme, in so far as facilities are available. Whole-time paid civil defence personnel would also be included in these arrangements. The patient would be expected to contribute through any contributory association to which he belonged or, if not a member of such an association, to pay such amount as he could reasonably afford towards the cost of his treatment, according to ordinary hospital practice.

Medicine Stamp Duties

In introducing the Budget on April 7 Sir KINGSLEY WOOD said that when the Finance Bill of July was being discussed the question was raised of the application of the purchase tax to medicines subject to the medicine stamp duty. It was pointed out that this involved a tax upon a tax, and comments were made on the medicine stamp duties themselves which, as his predecessor had told the House of Commons in 1939, had become administratively unworkable, and which it was highly desirable to repeal on that ground. The various interests concerned with the duties had come together and reached an agreement. He had consulted with the Minister of Health and, as a result, was in a position to announce that the Medicine Stamp Duties would be repealed. The Minister of Health would as soon as possible introduce legislation the object of which would be to maintain a fair balance between the interests of the pharmacists and of other vendors. The repeal would come into operation from September 2, so as to allow reasonable time for disposal of stamped stocks. We should part, therefore, with the Act of 1802 and other Acts in this matter, which, in process of time, had become a museum-piece of administrative complexity. The cost of this repeal would be £640,000 this year and £840,000 in a full year.

During the discussion on the Budget in the House of Commons on April 9 Captain ELLISTON said that the proposal to abolish the medicine stamp duties would mean the surrender of approximately £800,000 a year in revenue. He urged the Chancellor of the Exchequer to think again before he surrendered this sum which a great industry could well afford to pay. The Select Committee, which reported in 1936, while recommending that the duties should be simplified to remove anomalies, difficulties, and irregularities of administration, was of opinion that the trade was suitable for taxation and that a further large range of preparations should be liable. The Committee estimated that the turnover of the patent medicine manufacturers could be put at £20,000,000 a year, and that the taxation they proposed would yield not less than £3,300,000 a year. From the point of view of public health, the House of Commons was being asked to agree to proposals to remove a tax which, to some extent, acted as a check on extravagant indulgence in the habit of self-medication. If the duties were abolished it was notorious that there would be a marked increase in drug-taking and self-medication. These patent medicines, which could not now be sold under about 1s. 3d., would be put on the market in 6d. and 3d. packets. They would be obtainable from automatic machines and would cover the counters of the chain stores. They would be available in every grocer's shop. If the Chancellor of the Exchequer was determined to wipe out the Stamp Duty the House was entitled, before he did so, to have a Bill which, he understood, the vendors were ready to accept, which would control the advertisement of medicines and secure some measure of protection for the public.

Sir KINGSLEY WOOD said he would take into account what Captain Elliston had said. The proposals he had made in the Budget, if they were to be effective, must be contained in the Finance Bill, and he hoped that, as the interests concerned were in agreement, in any representations made to him it would be possible to maintain that agreement. Further debate on the Budget was adjourned until after Easter.

Decisions of Medical Boards

On April 8 SIR ERNEST GRAHAM-LITTLE asked the Secretary of State for War whether he was aware that dissatisfaction existed regarding the methods at present in force by which the Army authorities overruled the grading of recruits by the civilian medical boards; and whether he was aware that while two medical officers at least were required to reduce a recruit's category, one medical officer, unaided by a specialist or colleague, could raise that category. Captain MARGESSON said that instructions for the medical classification of soldiers were in process of amendment, the effect of which would be that the medical category of a recruit would not be altered during his first month's service unless the circumstances were exceptional. In regard to reclassification after that period, Sir Ernest Graham-Little would appreciate that, apart from possible changes in a man's physical fitness during the time that might elapse between examination by a civil medical board and calling-up, disability might only come to light during training. On the other hand, the conditions of Army life might improve the physcial fitness of a recruit to such an extent as to justify transfer to a higher medical category. Specialist advice was obtained by the Army medical officer where necessary.

Capitation Fee

On April 8 Mr. GROVES asked the Minister of Health whether further consideration had been given to the question of increasing the capitation fee payable to insurance practitioners, or granting them a *per capita* war bonus, having regard to the increased cost of living and the increased practice expenses, as well as to the fact that the fee was fixed on an insurance basis which had entirely changed by reason of so many of the healthiest insured persons being withdrawn from civil life and serving with the armed Forces. Mr. ERNEST BROWN replied in the affirmative. He said that the question had received full consideration. He had come to the conclusion that under present conditions he would not be justified in proposing an increase in the capitation fee.

Examination of Recruits to A.T.S.

Mr LAW informed Miss Ward, on April 8, that eighty women held commissioned rank in the R.A.M.C. The Ministry of Labour was responsible for the medical examination of men called up for the three Services under the National Service (Armed Forces) Acts as part of its general responsibility for the calling-up arrangements. As that Ministry was not responsible for the medical examination of recruits for the Auxiliary Territorial Service, this examination was normally carried out by R.A.M.C. women doctors, but, if a R.A.M.C. doctor was not available, a woman civilian medical practitioner was employed. He saw no objection to this arrangement, which worked well in practice and was calculated to secure the most economical use of medical personnel.

War Casualties

The approximate number of United Kingdom casualties from the beginning of the war to April 9 is:

Civilians

	Killed		*Injured and Detained in Hospital*
Men	13,712	Men	21,811
Women	12,112	Women	15,893
Children under 16	3,644	Children under 16	3,193
Unclassified	388		
Total	29,856	Total	40,897

Armed Forces

Killed and Missing	Wounded
37,607	25,895

Doctors Hard Hit by the War

Mr. GROVES inquired on April 10 what consideration had been given to the fact that doctors in danger zones suffered serious financial losses and experienced great difficulty in making a livelihood, and yet doctors in safe zones, by reason of evacuation, profited at the expense of the others. He asked whether some reasonable adjustment could be made so as to compensate the less fortunate doctors. Mr. BROWN replied that measures to meet the situation described, which was not peculiar to the medical profession, were primarily a matter for the profession itself rather than for the Government. The

Central Medical War Committee had acted so far as possible as a clearing house for the transference of doctors from evacuation to reception areas. The official arrangements for wartime medical services had also taken account of the special position of doctors in evacuation areas. For example, a number of those in coastal towns had been appointed to salaried posts in the Emergency Medical Service in their own towns or elsewhere. The number selected for commissions in the medical branches of the Forces was proportionately larger in the evacuation areas than elsewhere.

Medical Man-power

In reply to Sir FRANCIS FREMANTLE on April 10 Mr. BROWN said he had not yet established an organization for settlement of priority, as between the demands of the several Forces and Departments, for medical men, as recommended in January last by the Robinson Committee and urged by the Central Medical War Committee as essential to its work. The Service Ministers and the Secretary of State for Scotland and he awaited the results of the measures taken to carry out the other recommendations of the Robinson Committee. In the meantime they had not thought it necessary to set up any special priority organization. The matter would be kept under consideration.

Conditions at Prisoner-of-War Camp in Germany

Prof. SAVORY asked the Secretary of State for War whether he was aware that, according to the latest information, medical officers detained in camp Stalag XXA, in spite of the Geneva Convention, were suffering from having only one blanket in a temperature of 20° below zero; whether he would make representations to the German authorities through the protecting Power to provide extra blankets and also the necessary remedies for the destruction of the lice, described as ubiquitous; and, in view of the fact that while there was a cobbler's shop there was no leather and it was necessary for these officers to have repairs done to their boots, he would endeavour to arrange that leather should be provided.

Captain MARGESSON: Representations have been made to the German Government on both the first two points referred to in the question. There was a general shortage of leather in Germany, and in some cases wooden soles were being used as a substitute. The number of pairs of boots sent to the International Red Cross Committee for distribution to British prisoners of war was 97,125, and there had recently been a considerable improvement in the state of footwear in the camps. A further consignment of boots was at present on its way from this country.

Anti-gas Ointment.—Asked on April 3 about the supply of ointment for dealing with the effects of blister gases, Mr. HERBERT MORRISON said that bleach ointment had been on sale for some time. Anti-gas ointment No. 2, which was better, was now procurable through any chemist. To meet the needs of members of the public who did not provide themselves with a supply of ointment, arrangements had been made for bleach cream, which could not readily be carried in small containers, to be available in the event of emergency at chemists' shops. He would consider whether it was possible to supply a small pocket outfit to wardens and other civil defence workers.

Calcium in Wholemeal.—Mr. LEVY asked on April 9 whether the Ministry of Food was aware that the phytic acid in wholemeal used up all the calcium contained in it, and whether they would consider the addition of calcium to the Ministry's wholemeal loaf to protect consumers against rickets. Major LLOYD GEORGE did not accept everything in Mr. Levy's question, but said that his suggestion was under active consideration.

Cost of Diphtheria Immunization.—Answering Mr. Creech Jones, Mr. BROWN said on April 10 that the cost of immunization fell under the two main heads of payment for medical services and cost of prophylactic material. As the work might be carried out in part by local authorities' own salaried medical staff and in part by general practitioners under varying financial arrangements with local authorities, it was not possible to estimate expenditure under this head. The cost of supplying prophylactic was estimated at about £7,000 per million children, or rather more than 1½d. per child.

Blood Donors.—Local appeals for blood donors have been organized where necessary by the blood transfusion officers serving in the Emergency Medical Service in each region. Mr. Brown is advised that the number coming forward as a result is adequate except in a few isolated instances. In these cases help is obtainable from a neighbouring town. Mr. BROWN said on April 10 that the matter could safely be left in the hands of the regional blood transfusion officers, and that no special appeal by him was necessary.

Fees Paid to Medical Boards.—On April 8 Mr. BEVIN told Mr. Groves that the total sum paid in fees to members of recruiting medical boards in the twenty-one months up to February 28 last was about £1,199,350. He could not state, without making a detailed inquiry, the maximum and minimum amounts paid to individual doctors or the total number of doctors who at some time during the period participated in the work. The number of doctors at present on the panels of medical boards was 3,724.

Medical News

Dr. O. R. Tisdall will read a paper on "The General Practitioner and Scientific Thought" before the Royal Society of Arts (John Adam Street, Adelphi, W.C.) on Wednesday, April 30, at 2.30 p.m. Viscount Dawson of Penn will preside.

A meeting of the Medico-Legal Society will be held at 26, Portland Place, W., on Thursday, April 24, at 5 p.m., when J. C. M. Matheson will read a paper on "Infanticide."

The seventeenth annual meeting of the American Association of the History of Medicine will be held at Atlantic on May 4 to 6 under the presidency of Dr. Esmond R. L Henry Phipps Institute, Philadelphia.

The Duke of Kent, president of King Edward's Hos Fund for London, in a broadcast talk on Easter Monda the work of the hospitals since the war started, spoke o damage suffered from enemy bombing. "The hospitals; he kept going and going strong, because there were brave devoted men and women who were determined to overc any difficulties.

At a dinner held in a Scottish town, attended by se medical officers of the Polish Army, the Director-Genera the Military Medical Service of the Republic of Poland sented to Colonel A. Irvine-Fortescue, D.S.O., M.B., illuminated diploma and enamelled cross of the Polish r tary distinction known as the Odznaka Sluzby Zdrovia (ba of medical service). In making the presentation the Po D.-G. said that the whole Polish Medical Service in Bri knew Colonel Irvine-Fortescue well, and paid tribute to work in helping the organization of the Service.

The Manchester Jewish Hospital, which was forced to s pend its work for two months owing to damage to part of buildings, is once again admitting patients, and half of beds in the hospital are already in use. It is hoped to m up the full complement of beds in the next few weeks.

At a recent Court of Governors of Bethlem Royal Hospi it was announced that Queen Mary had consented to nominated president of the hospital. The foundation of t hospital dates from 1247 in the reign of Henry III, and charter, which embraces its sister hospital, St. Bartholomew was granted by Henry VIII in 1547. The revenues are no devoted to the maintenance of the hospital at Monks Orchar near Beckenham, Kent, opened by Queen Mary in July, 19 where patients suffering from nervous and mental disorde are received and treated on the most modern principles, ar where a centre of active research has been established throug the generosity of its former president, the late Lord Wakefie

The late Mr. Herbert Tilley, F.R.C.S., who left £101,2 (net personalty £97,485) bequeathed £800 to the Royal Ear and Throat Hospital, University College, for the upkeep of the Herbert Tilley Museum, and £200 upon trust for an annual lecture, and £1,000 to the Royal Medical Benevolent Fund.

Prof. Henry Sigerist of Johns Hopkins University and Dr. Esmond R. Long, president of the American Association of the History of Medicine, have been elected honorary members of the History of Medicine Athenaeum of Buenos Aires.

The scientific report of the Royal College of Surgeons of England for the year 1939–40, presented by the Conservator, Prof. John Beattie, indicates briefly part of the work carried out by the museum department and by the research laboratories between October 1, 1939, and September 30, 1940. The pathological curator and various members of the technical staffs remain absent on military or national service. A sustained inflow of specimens during the year is recorded with satisfaction. Though the museum is now closed, it is hoped that Fellows, Members, and other friends may continue to bear in mind its needs, even though specimens presented now cannot be critically examined or mounted until the end of the war.

One hundred girls are to be formed into a mosquito squad in Queensland for fighting mosquitoes in military camps. They will be specially trained in hygiene and other subjects

Canada is setting up a "blood bank" to provide transfusions for 20,000 military and civil casualties.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

One hundred and sixty-eight fewer cases of measles were reported than in the preceding week. But, despite the general downward trend, increases have been notified from some areas. The following figures show the extent of the increase over those for the preceding week—Nottingham, Worksop R.D. 67; Staffordshire, Brierley Hill U.D. 67 and Rowley Regis M.B. 53; Warwickshire, Birmingham C.B. 160; York. West Riding, Leeds C.B. 54 and Hemsworth U.D. and R.D. with 22 and 20.

Diphtheria showed 31 notifications in excess of the previous week. A fall of 16 in the notifications of scarlet fever was recorded; but in Staffordshire the returns rose from 41 to 77, and in Lancashire from 173 to 196. Of the 24 cases of enteric fever notified in England and Wales 12 were returned from Northamptonshire (10 from Brixworth R.D.). There was no change in the total notifications of cerebrospinal fever; the county of Chester showed an increase of 10, and London and Swansea both returned 7 more cases than in the preceding week. The number of cases of dysentery decreased by 18, although fresh outbreaks were reported from several areas, the largest being Essex, Witham U.D. 9; Gloucestershire, Bristol C.B. 6; Yorks, West Riding, Wortley R.D. 12.

Whooping-cough

There were 4,319 notifications for the week ending March 22, a rise of 981 on the preceding week. This is the largest figure recorded since the returns of whooping-cough were first published in November, 1939. The rise was fairly general throughout the country, the largest increases being reported from Lancashire, Leicestershire, and Yorks, West Riding, with, respectively, 75, 57, and 93 more cases than in the previous week. The eastern counties have a low incidence—Suffolk 23, Norfolk 14, and Lincoln 14—and very small numbers are recorded from the south-western counties of Dorset 10, and Cornwall 9.

Returns of the Registrar-General for Scotland

The publication of the returns for the fourth quarter of 1940 include a preliminary return for the year. The birth rate of 17.1 per 1,000 for the year was the lowest ever recorded in Scotland. The death rate was high, 14.9 per 1,000, being 1.7 above the average for 1935–9. Infant mortality was 78 per 1,000 live births. This was a higher value than that recorded in the two preceding years, but with two exceptions lower than for all years before 1938. Deaths from scarlet fever 35, and whooping-cough 197, were the lowest ever recorded in Scotland for these diseases. The deaths from measles 262, diphtheria 676, and influenza 1,801 were respectively 25, 246, and 577 above the average for 1935–9. Deaths from cerebrospinal fever numbered 482, against 61 in the preceding year, and was the largest number registered as due to this cause since 1907.

No. 12

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended March 22.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1941 (a)	(b)	(c)	(d)	(e)	1940 (Corresponding Week) (a)	(b)	(c)	(d)	(e)

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.) Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE NO.—B.M.A. and *B.M.J.*: EUSTON 2111.

TELEGRAPHIC ADDRESSES.—EDITOR, *Aitiology Westcent, London*; SECRETARY, *Medisecra Westcent, London.*

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

QUERIES AND ANSWERS

Income Tax

Fall in Partnership Income

"X. Y. Z." carry on a practice in a defence evacuation zone and the receipts have suffered accordingly. The assessments have been on the cash basis. How should the income from the partnership be calculated?

*** It should be borne in mind (*a*) that the special relief to falling incomes does not affect liability to assessment on the previous year's basis, though it gives relief from the severity of the tax so assessed; (*b*) that the claim to relief must be made by an individual, in respect of his total earned income, and not by the firm as such. "X. Y. Z." should therefore compute the adjusted profit of the firm for 1940–1 and the division between the partners as if for the 1941–2 assessment. Each partner should then make an individual claim to relief for 1940–1 (assuming that the 20% reduction condition is complied with) to the local inspector of taxes, who will arrange accordingly. The fact that the firm's accounts are on the cash basis is not likely to create difficulty; actually it would tend to slow down the effect of the reduction in earnings.

Travelling Expenses—Appointment Books and Examination Fees

"J. F." holds an appointment as physician to an infirmary and continues to act as assistant physician to another infirmary. It was one of the conditions of the new appointment that he should be allowed to continue the duties of the former one. Can he claim travelling expenses? Also, can he claim expenses incurred on books, etc., in connexion with his study for a further degree?

*** It was held in a very old case that the expense of travelling from a residence to the place where the duties of an office are performed is not allowable. If the duties are carried on in more than one place (e.g., those of a Member of Parliament) the cost of travel from one to the other is allowable. Consequently, if the condition of carrying on his former duties were laid upon him by the authority from whom his new office is derived, "J. F." could by analogy, in our opinion, claim some allowance But we gather that that is not quite in accordance with the facts. The expenditure on books, examination fees, etc., represents capital outlay and is not allowable.

Part of Premises Let

"N." has let two sections of his house to tenants, in substantially an unfurnished condition. How does this affect his liability?

*** In the first place assuming that he still uses the same rooms as before for professional purposes (and to the same relative extent) the lettings will not affect the deduction to be made in calculating his professional earnings He is, however, apparently liable to account for tax on the additional monetary advantage he is deriving from the letting. The precise amount is a matter of calculation, the basis of which is that he is liable to assessment, as for unearned income, at a sum representing the excess of what the net Schedule A assessment would have been on the facts as they now stand over the actual assessment of £122. Probably the best course for "N." to follow is to send a statement of the facts to the local inspector of taxes and await the result.

LETTERS, NOTES, ETC.

Complications after Chemotherapy in Pneumonia

Dr. J. GRIMSON (London, N.3) writes: Since the introduction of sulphapyridine in the treatment of pneumonia many physicians, both in specialist and general practice, have noted the relative increase in the incidence of empyema and delayed resolution in cases treated by this drug from the immediate onset of symptoms. Bearing this in mind, I have recently delayed giving the drug until within forty-eight hours of the expected time of cr In every case so treated a typical crisis has occurred and th have not been any complications. I quite realize that a such cases do not prove very much, but I think these observati are worth recording.

Treatment of Scabies

Dr. W. F. COOPER (London, S.W.20) writes: Dr. H. M. Bernca (January 25, p. 135) describes the use of sulphur. *Scabies see* to be becoming extremely prevalent, apparently due to shell and carried from one person to another. Anyhow, the treatm is very important at the present time. I can confirm I Berncastle's experiences, as I have had sufficient personal expe ence. There is evidently a very important difference betwe plain sulphur and the ointment. Plain sulphur, flowers ground, oxidizes to the dioxide in moist air, but when ea particle is surrounded with grease oxidation is prevent Actually one can smell the sulphur dioxide when the powder exposed; and that is one of the finest *insecticides.* Sulphur the greatest and by far the most common of all insecticides. is used for animals in tremendous quantities. It is used f trees, plants, and so on—also in great quantities. If the bo and clothes are dusted with the powder, finely ground, the cu *is simple* and certain, at least in my experience. It is just efficacious against lice and bed-bugs. When I get an infecti myself I dust all clothes, blankets, bedding, etc., with it. F mattresses I use coir, which I dust freely, and place betwe folded sheet or rug, and fasten with safety-pins; then th *dressing can be repeated as desired. Coir* is good because can be boiled and dried repeatedly. I have been infecte many times abroad, but I never worry, for I never go witho some sulphur. But whether it really is as excellent as I find can only be known by repeated experiments carried out und proper medical supervision. It should be good to sprinkle i shelters, and for that work probably the solution in an alkalin salt would be best, sprayed. The sulphur is precipitated as very fine powder. It is in this form that *it is* used so muc for trees, plants, etc. The use of sulphur by mouth is a very ol remedy. I think it is one used by the Assyrians or before then The confection of the brimstone and treacle is also a mo excellent laxative for anyone, especially children.

Varicose Ulceration

Dr. STUART MCAUSLAND (Liverpool) writes: It is probably the ex perience of others like myself who have large varicose vein and ulcer clinics that occasionally ulcers become reluctant to heal with the known methods of compression with sponge rubber and tight bandaging with "elastoplast." Recently I have found that such ulcers respond remarkably well if packed lightly with three or four layers of a dressing consisting of an open mesh gauze impregnated with petroleum jelly and balsam of Peru— the sponge rubber and elastoplast being then applied on the top of the dressings. In order to allow free discharge through the layers of the dressing, and in order to avoid disturbance of granu lations on removal, it is essential that the gauze have an open *mesh of about 2 mm.*, and that it be thoroughly impregnated with the petroleum jelly mass. This type of gauze is actually commercially prepared, being sold on the drug market under the name of "jelonet." I have used this preparation for some six months, and these indolent ulcers do fill up more rapidly as a result. It is, of course, important that an adequate amount of sponge rubber should be used. If there be much brawny thickening of the leg surrounding the ulcer it is a good plan to cut a small piece of the rubber to the size of the ulcer, and then to lay over it a very large piece of sponge rubber, which exerts pressure over the whole red, oedematous, and brawny area. The method also of bandaging is important. I am a great believer in the value of the "stirrup"—that is, a strip of elastoplast running down the side of the calf, under the arch of the foot, and up the other side of the calf, thus covering the whole rubber over the ulcer, which is usually lateral. A back strip of well, terminating under the foot, is then applied. Then the whole lower leg from the toes upwards is firmly bandaged. The value of the back and side strips is that they prevent creasing of the skin by the upward horizontal bandaging, and thereby avoid much discomfort for the patient.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY APRIL 19 1941

DOCTORS AND THE WAR DAMAGE ACT

As finally passed by Parliament, the (voluntary) chattels insurance sections of this Act provide free insurance for every householder up to a limit of £200, with an extra £100 if he or she is married, and £25 more for each child under 16. Non-householders obtain free insurance up to £50. These sums are payable after the end of the war, but carry 2½% interest from the time when the damage takes place.

Above these free limits, there is a premium of £1 % per annum up to a total of £2,000, £1 10s.% for the next £1,000, and £2% for the next £7,000; this is the maximum for which insurance can be obtained. Insurers must take out their policies with one of the recognized companies, or through Lloyd's, within one month of the coming into force of the scheme, which is now fixed for May 1. As no commission will be payable to agents, the Medical Insurance Agency cannot grant any rebates to those who take out policies under the Act; but members of the profession will nevertheless be wise to utilize the Agency, not only for advice as to the amount of their policies but with a view also to the help that can be given in getting prompt and satisfactory settlement of any claims that may arise. Policies must be for the full value of the chattels insured.

The medical profession also comes under the "business" scheme of the Act, but only in respect of professional equipment. This part of the Act is optional if the equipment is of less value than £1,000; compulsory if above that figure. There is no free insurance in this section, and those who do not insure will get no compensation. *It is still not clear* whether motor cars used in the practice come under these clauses concerning "professional equipment."

There are provisos limiting the amount of the claims that will be admitted in respect of works of art, gold and silver plate, jewellery, furs, books more than fifty years old, and so on. They are similar to the limitations laid down by many existing fire insurance companies, and may be regarded as part of normal insurance procedure.

Correspondence

A State Medical Service

SIR,—I have read with great interest and gloomy foreboding the detailed scheme for State Medical Service by Dr. Pybus (*Supplement*, March 15, p. 29). I should be glad if you would allow me to indulge in a little destructive criticism and to offer an alternative scheme. I submit that the scheme as outlined is too much of a medical Utopia. The following generalizations occur to me:

1. It has been shown time and again that medicine and bureaucracy are incompatibles.

2. General practice and consultant practice are two completely separate entities comparable to solicitor and barrister branches in law, and only slightly amenable to the system of promotion obtaining in the brother professions—the Church and the Services.

3. To say that private practice will in time die out altogether smacks too much of a medical dictatorship. There will always be patients and doctors who prefer to remain outside any scheme. They must be recognized and provided for.

4. The tradition of individual freedom must be preserved.

5. A panacea for all the ills suffered by the profession will not be found in a day or a year. The perfect plan will evolve from a small change, and by a process of adaptation, selection, and survival of the best and fittest arrive at great things.

6. General practice is the foundation stone of the whole structure of the profession upon which all schemes and plans must be built.

7. General practice is a generic term covering widely differing types. A practice may be urban or rural, or both. It may be situated in a wealthy, good, middle-class, poor, or depressed industrial district. One scheme will not meet the needs of all.

8. A State service for those with incomes under £250 or £500 in opposition to private practice as we now know it would produce a further schism in the profession, and is to be avoided at all costs.

9. A fixed salary destroys initiative and ambition. No one expects or hopes to make a fortune out of medicine, but for too long there has been a tendency among reformers to underrate the value of the work done by the profession as a whole. It must be remembered that every member of the profession is expected to maintain a high standard of appearance, most have families to educate and provide for, and there is always old age to be made secure.

I suggest the following alternative scheme, the aims of which would be: (1) to ensure that all the amenities of medicine are within reach of every member of the community; (2) to enable the profession to regain, retain, and maintain full control of all that which appertains to medicine.

There would be four stages in the evolution of the scheme:

Stage 1.—Contributory medical service would be adopted on a wide scale—that is to say, all general practice services now covered by the visiting and consultation fee would be covered by one quarterly family contribution, the amount of the contribution to be arranged between patient and doctor. In the case of the very poor the contribution would be made by the local authority. The old medical societies would be revived and new ones formed to administer the scheme, while the "donkey" work would be done by the local health offices.

Stage 2.—The medical society in each district would select and invite a group of consultants and specialists to join the society on the understanding that they would henceforth take their part in the evolution of the scheme. The local M.O.H. would, of course, already have been invited, and would form a most valuable link between the society and the Ministry.

Stage 3.—The growth of the clinics. The local authorities would cause to be built as many small clinics, at each of which three, four, or five doctors would work, as might be necessary according to the size of the district and the density of the population. The clinics would be fully equipped and staffed with nurses by the local authority. Each doctor would rent his consulting-room. These would be the sub-clinics. There would be in each district one central clinic, the headquarters of the local medical society. This would include outpatient departments, hospital with private block, maternity hospital, private waiting and consulting rooms, and nurses' home. All cases, with the exception of casualties, would first be seen and sent from a doctor at a sub-clinic. The administration of the central clinic would be carried out by the members of the society themselves. The M.O.H. would act as medical superintendent, with his staff of office clerks doing the clinic business, and beyond him the Ministry acting as eternal guide, philosopher, and friend. The acting medical staff would be appointed from those general practitioners who applied and were elected to the various posts; the consulting staff would already have been invited, and might, of course, be added to at any time or replaced as they moved up the ranks as consultants. The practitioner in charge of the case at the sub-clinic would be able, if he wished, to continue to care for it at the central clinic even if he was not on the acting medical staff. House officers would be appointed in the various departments of the clinic.

Stage 4.—The whole country would be divided into regions, and in each region there would be one general teaching hospital with as many satellite hospitals as might be necessary. All central clinics in each region would be attached to the general hospital. These would be staffed by consultants who would fill their beds from cases seen at the clinics. At first the consultants would be attached to clinics in various regions (it may not be clear that a consultant or specialist may be attached to several clinics), but in time it would be found that, as the new men came along, the hospitals and clinics would be strictly regional. The general hospitals, their satellites, and the sites they were built on would become the property of the State. The highest administrative posts in each hospital would be State-paid, and should be regarded as the plums of the profession. The consulting staff of the hospitals would remain ordinary members of the profession not under State control. This is analogous to the courts of law, where some members of the legal profession are Crown servants and others not. The administration of the hospitals would be in the hands of the members of the staff.

As to the finance of the scheme, three funds would be established: general practitioner, consultant, and hospital. The public would make contributions to the first two only, while the State would contribute to all three. The contributions made into the general practitioner fund by each family would vary in the same manner and for the same reasons that the present visiting and consultation fees vary. That is to say, they would be arranged to the mutual satisfaction of patient and doctor at or above a minimum figure to be settled by the medical societies. The society's almoner would decide in cases seeking the help of the local authority for all or part of their contribution. Freedom of choice remains common to patient and doctor. The amount due to each doctor would be calculated from the amount contributed by each family on his list.

Each family contributing to the general practitioner fund would contribute an amount equal to one-quarter of this contribution to the consultant fund. This fund would be collected and administered in the same way as the general practitioner fund. It would provide a retaining fee to each consultant and specialist attached to the central clinic, a modified fee for each case seen or treated at the clinic, and also full maintenance costs for each patient receiving treatment at the clinic or general hospital. In cases of necessity the State would make these contributions also for the family.

Contributions and payments to the general hospital fund would be made by: (1) the central clinics, from both the above funds as a form of voluntary levy; (2) the consultant fund, for maintenance costs and consultants' fees; (3) existing endowments, etc.; (4) student fees; (5) the State, if necessary a grant made in the form of a contribution. This fund would provide the salaries of all employed at the hospital and the maintenance cost of each patient, also the retaining fees of the consulting staff and the consulting, etc., fees due to them. It would not include the salaries of the State servants holding high administrative posts.

I suggest that this alternative scheme fulfils the two original aims and would improve conditions throughout the whole profession. Not only would the patient know exactly what his bill of health for the year was to be, but he would be far more likely to remain in the hands of one doctor and see him early in his illness. The doctor would know who his patients were and that he could see them as frequently as he wished to. He would thus be able to practise preventive medicine on a much larger scale. His practice would increase enormously in value, while his increased income would allow him to take reasonable holidays and leave for postgraduate study, and also to employ all the assistance he needed. Not only would the scheme absorb all members of the profession now in practice: it would also create an enormous demand in the ranks of general and consultant practice.—I am, etc.,

Beckenham, April 7. ALAN MARSH.

SIR,—I welcome the extremely sound and well-balanced letter by Surgeon Lieut. Peter Shutte (*Supplement*, April 5, p. 41), a man from my own hospital. I thoroughly endorse all that he says and I feel that he has cleared away a great deal of rotten wood. The fact remains that whether we eventually wear the peaked caps and brass buttons of a State service or not, the great bulk of medical work in this country will consi similar work to now, conducted in a similar way—th family or general medical practice. It is extremely dif to see, therefore, how such a metamorphosis as Dr. Pybus outlines can bring about any great or radical imp ment. It is likely to produce a semi-paralytic, time-serving tapish type of public servant. The practice of medici essentially a personal affair between patient and doctor. extension of the panel system with great improvements (forbids outlining these here) is to be visualized and is a re able form of evolution. The local hospitals should cea be mere privileged hunting grounds and private preserve the few, but should be thrown open to all practitioners i area, thus assuring that all practitioners should take pa the work of their local hospital and should work in touch with it.—I am etc.,

Oxford, April 7. CHARLES A. H. FRANKLYN, M.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Section of Medicine.—Tues., 4.30 p.m. Discussion: Nature and Treat of the Effort Syndrome. Openers, Dr. H. J. Starling, Dr. Paul W Dr. Aubrey Lewis, and Dr. Maxwell Jones.

General Meeting of Fellows.—Tues., 5 p.m. Candidates for election to Fellowship.

Section of Comparative Medicine.—Wed. 4.15 p.m. Annual General Mee Election of Officers and Council for 1941-2. Discussion: Swine Influ in the British Isles. Opener, Mr. F. Blakemore. Paper by Miss M Macfarlane and Dr. B. C. J. G. Knight: Some Enzymic Activitie *Cl. welchii* Toxins. Members of the Section of Pathology are spec invited to attend the meeting.

Clinical Section.—At British Postgraduate Medical School, Ducane Road, Thurs., 3 p.m. (Cases at 2.15 p.m.)

Section of Orthopaedics.—At Wingfield-Morris Orthopaedic Hospital, Hea ton, Oxford, Sat., 11.30 a.m. Papers by Dr. A. H. Robb-Smith and J. C. Scott, Fat Embolism; Mr. W. B. Foley, Report on Cases of Sc Arthritis. 2 p.m., Dr. J. M. Barnes and Mr. J. C. Scott, The Sprea Bacteria and Toxins from Infected Wounds—the Clinical Application Laboratory Findings.

Section of Physical Medicine.—At Chertsey Sat., 2.30 p.m. Discuss Observations on the Value of Electrodiagnosis and Electrotherapy Peripheral Nerve Lesions. Opener Dr. P. Bauwens.

DAVYHULME MILITARY HOSPITAL MEDICAL SOCIETY.—*Thurs.*, 3 p.m. cussion: Vincent's Angina. To be opened by Captain J. Winter. Med men and women in any Services (including civilian) will be welcomed.

Diary of B.M.A. Central Meetings

APRIL

23 Wed. Council, 12 noon.

MAY

1 Thurs. Journal Board, 2.15 p.m.

B.M.A.: Branch and Division Meetings to be Held

LANCASHIRE AND CHESHIRE BRANCH: BIRKENHEAD AND WIRRAL DIVISION. At Pensby Hotel, Pensby, Sunday, April 27, 5.30 p.m. Annual Meetin Election of Officers. 6 p.m., Meeting of all medical practitioners in the ar of the Division for election of Local Medical War Committee.

APPOINTMENTS

MCINTYRE, C. M., M.B., Ch.B., Medical Referee under the Workmen's Co pensation Act, 1925, for the Island of Islay (Sheriffdom of Argyll).

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. Th amount should be forwarded with the notice, authenticated with the name a address of the sender, and should reach the Advertisement Manager not lat than the first post Tuesday morning to ensure insertion in the current issue

MARRIAGES

SYMONDSON—LEWIS.—On March 8, at Rhiwbina, Cardiff, Captain J. L Symondson, R.A.M.C., to Alicia Lewis, M.B., B.Ch., Hunecott, Kingsbridge Devon.

WILLIAMS—PASCOE.—At St. Pancras Church, Thursday, April 10, Hargreaves Harley Williams, M.D., to Elizabeth Mackay Pascoe.

SUCCESSFUL GRAFTING OF ADRENAL GLAND IN A CASE OF ADDISON'S DISEASE*

BY

F. KATZ, M.D.

AND

F. MAINZER, M.D.

Directors respectively of the Surgical Department and the Department of Medicine, the Jewish Hospital, Alexandria

The results of transplantation of adrenal tissue in numerous animal experiments do not, on the whole, encourage the use of this method in cases of adrenal insufficiency in man. Moreover, the operation on the animal is carried out under ideal conditions, whereas in man the recipient of the graft is usually extremely ill and the choice of donor is also necessarily limited. Clinical reports of unsuccessful attempts to treat Addison's disease by transplantation of the adrenals are frequent in literature, and even the few reports of successful transplantations are not above criticism.

In the first place, unmistakable proof is needed that the case is one of Addison's disease. Thus, in one case which had been apparently cured by transplantation treatment the eventual necropsy showed that the adrenals were healthy while the graft had decayed (Conybeare and Mills, 1924). Again, in view of the well-known clinical variations in the course of the disease, short periods of improvement with increased blood pressure should not be considered to be the result of transplantation therapy. Transplantation should not be looked upon as clinically successful unless there is a definite improvement extending over a period of months in a case of undoubted Addison's disease. So far as we are able to judge there are no more than five cases in the literature which fulfil this requirement. These are the cases of Reinhart (1928), Halperin and Arkuschenko (1927), Leschke (1928), Beer and Oppenheimer (1934), and Goldzieher and Barishaw (1937). The periods over which these cases were observed subsequent to operation varied from five months to one year.

We are able to add a sixth case to this list—a successful grafting in an indisputable case of Addison's disease, although an atypical one owing to the absence of pigmentation. The patient was under our observation for nearly three years before operation and for fifteen months since operation.

Case History

The patient, a woman aged 56, had undergone hysterectomy at the age of 34 on account of persistent haemorrhage due to myoma. Apart from this she had apparently been healthy, and had had two normal pregnancies. The disease for which she was eventually treated by grafting began very gradually ten years earlier, progressed slowly, and was interrupted by periods of improvement. She became languid and easily fatigued, took less interest in her environment, and became indifferent even with regard to her own health.

The physical symptoms during the course of years included intermittent intestinal disturbance accompanied by painless diarrhoea, which had been mistaken for and treated as enterocolitis. *X*-ray examination of the intestinal tract revealed nothing abnormal. The blood pressure, which had not been taken before the onset of the disease, was always low—between 80 and 90 mm. Hg—and during the more severe phases it was below even this level. The disturbances of temperature were characteristic. The Egyptian winter, generally regarded as agreeably temperate, seemed to her unpleasantly cold. Her body temperature under normal conditions was low—about 97° F. taken rectally—and even during acute infectious illnesses it hardly ever rose above 100.4°. Moderate wasting became unmistakable, even in the early stages of the disease, and increased rapidly in the later stages. The patient lost 22 lb. in the course of six years, half of it in the first six months of 1935. She often suffered from nausea, though vomiting did not actually occur, and she complained of "rheumatic" pain in the musculature of the back.

Two incidents in this history were noteworthy. In June, 1935, she had severe pain in the upper abdomen, the stools assuming a whitish sheen, but there was no jaundice, and the urine on examination was normal. This condition persisted for a week, and was treated as "liver colic" by her doctor. Some months later an attack of "oppression of the heart" occurred, the pain radiating into the left arm. During both these incidents the blood pressure was found to be below 80 mm.

For a time the patient had intravenous injections of glucose, and always felt particularly well for some hours subsequently. To combat the emaciation insulin was given, but even 3 units gave rise to symptoms of overdosage—profuse sweating, tremor, dizziness, and faintness—and had to be discontinued. Such attacks, which resembled angina pectoris, were treated by withdrawal of salt, but the effect of this measure was a rapid increase of weakness, somnolence, muscular pain, and nausea, so that the patient had to return to her usual food, which contained salt at random.

During 1935 all the above symptoms became more pronounced. Malignant tumour was suggested, but examination revealed only a trophic ulcer of the vagina, which on histological examination gave no sign of malignancy.

It was at this time that we first saw the patient. Her bad general condition and cachectic fatigued appearance were noted. There was no abnormal pigmentation or distribution of hair. The blood picture was as follows: erythrocytes, 3,900,000 (later 3,400,000) per c.mm.; haemoglobin, 75% (later 68%); leucocytes, 7,500 per c.mm.—neutrophils 55%, lymphocytes 41%, eosinophils 1%, monocytes 2%, band-like polymorphs 1%. The Wassermann reaction was negative. The blood sugar was 100 to 115 (later 91) mg. per 100 c.cm. The electrocardiogram showed no marked deviation from the normal, and a radiograph of the renal area gave no indication of calcified glands.

Treatment with anterior pituitary extract over several weeks was without result. The administration of cortical extract was then started, the patient receiving daily, and later every second or third day, intravenous injections of 10 c.cm. The result was immediate and impressive: the weakness, muscular pain, and somnolence disappeared, and within two months the patient had put on 11 lb. in weight.

*Abridgment of paper received from Egypt.

For one year all went well, and it was possible to reduce the extract to 20 to 30 c.cm. a week, given intramuscularly. Then a severe crisis occurred following some days of over-exertion and domestic worry. There was nausea with frequent vomiting and fatty diarrhoeic stools, and the abdominal musculature was rigid and painful to pressure. Blood pressure dropped to 70 mm. In view of the patient's very thin veins and the collapsed circulation, intravenous administration of considerable amounts of fluid could not be undertaken Fluids (1,200 c.cm.) with 20 grammes of salt were given daily, mostly by mouth and to a small extent rectally. The patient received daily 80 c.cm. of adrenal extract (cortin and eschatin), and with eventual improvement the amount was reduced to 70 and later to 50 c.cm a week, given intravenously. But the former condition of comparative ease could not be regained. The patient's complexion became more yellowish, with a clay-coloured tinge, and freckle-like spots appeared on the backs of the hands and on the face; but the typical Addison pigmentation was not shown, nor was there at any time pigmentation of the mucous membrane of the mouth.

The Operation and After

This was the condition until August, 1938, when a severe Addisonian crisis occurred, due immediately to the damp heat prevailing at that time in Alexandria (86°, with 95% humidity). The amount of extract was increased to 40 c.cm. daily, but the blood pressure dropped to 70 mm.

In this crisis it was decided to graft into the patient the left adrenal gland of a man who had died just previously from a cerebral tumour. The donor was 52 years of age, and belonged to the same blood group as our patient. The graft was made in the abdominal musculature on the left side, under local anaesthesia.

[Here followed in the complete paper a detailed description of the operation.]

Soon after the operation the symptoms of adrenal insufficiency reached their climax—increased somnolence, uncontrollable vomiting, frequent diarrhoeic stools, collapse of circulation, and fall of blood pressure to 60 mm., this in spite of the fact that the daily administration of extract had been increased to 80 c.cm. and that of salt to 50 grammes. Within three days of the operation, however, the condition improved, the dose of extract was reduced, and no more was given after the seventh day, and the patient declared that she felt absolutely well. She left hospital on the sixth day after the operation. During the next two months the blood pressure varied between 115 and 135 mm., the colour of the skin became lighter, and the freckle-like spots were no longer so intensely coloured. But any great exertion or excitement always produced slight somnolence and pain in the back, and during an influenza attack, when the blood pressure was lowered to 80 mm., it was necessary to give 10 to 20 c.cm. of extract for some days.

Comment

From the results of experiments on animals it seems irrelevant to the success of the operation where the grafting takes place (ovary, testis, kidney, musculature), nor does the type of transplantation (whether the organ is cut into slices or grafted as a whole) seem to be of significance. As the operation has been shown to be more likely to succeed in some species of animals than in others, it may be that in man the conditions are exceptionally unfavourable. It has been demonstrated in a great number of animal experiments (Loeb, 1930, 1937) that transplantation in general is more successful the closer the blood relationship between donor and recipient, and in respect of the adrenal gland in particular this has been recently emphasized by several workers (Ingle and Higgins, 1938; Ingle, Higgins, and Nilson, 1938). When selecting the donor the utmost the surgeon can do is to consider the blood group.

The result of the grafting operation must be largely dependent on the bodily condition of the recipient, and in Addison's disease particularly it must not be lost sight of that the insignificant surgical procedure of grafting endangers the patient's life. Treatment by extract before, during, and after the operation has therefore undoubtedly improved the prospects of success.

In our patient the adrenal graft is able to meet the requirements of normal life, but if the demand is above normal it fails. This cannot be due to the fact that there is only one adrenal gland fully functioning, because such symptoms of insufficiency are not met with in cases in which one adrenal gland has been removed by operation. On the contrary, there is complete accordance between our observations and those on the functional behaviour of grafted adrenals in the animal (Ingle, 1937; Perla and Gottesman, 1931a, 1931b; Wyman and tum Suden, 1937).

Summary

In a severe case of Addison's disease the adrenal gland of a patient belonging to the same blood group, who had just died, was grafted into the abdominal musculature. The functional results, as observed over a period of fifteen months after operation, are excellent. A state of compensation has been produced so long as the patient lives under normal conditions. Only after special exertion or during a transitory infection, with increased demand on the adrenal gland, are slight signs of insufficiency noted.

TREATMENT OF 100 WAR WOUNDS AND BURNS

BY

JAMES A. ROSS, F.R.C.S.Ed.
Captain, R.A.M.C.

AND

K. F. HULBERT, M.B., B.S., D.A.
Lieutenant, R.A.M.C.

During recent enemy activity over this country 100 wounded men have been under our care in a military hospital. The great majority were admitted within six hours of injury, unlike those described in previous articles on surgery in the present war (Cohen and Schulenberg, 1940; Brown, Dennison, Ross, and Divine, 1940).

Some 50 of our patients were airmen, both Allied and German. They were brought in within an hour or two of their injury. Excited, with nerves still keyed to the highest pitch, with heads still spinning from the swift rush earthwards, and with wounds bleeding freely from the battle, they formed a striking contrast to the Dunkirk soldiers with their grimy and inflamed wound holes often several days old.

These cases afforded an opportunity of carrying out modern treatment and, as some were in for several weeks, for observing their clinical progress. The preliminary anti-shock measures—warmth, morphine, hot fluids—were necessary in all except trivial cases. Some patients required either blood or plasma. When salines were indicated we often used the intramuscular route for injection in order to eliminate the risk of oedema of the lungs (Billimoria and Dunlop, 1940). The problem of assessing

the precedence for operation, so important with a rush of casualties, did not concern us: with small numbers coming in there was always adequate time to deal with each case separately.

Wounds of the Limbs

Wounds of the limbs constituted the greatest number of our cases, the majority being compound fractures. Complete excision of the wound layer by layer was undertaken in these cases if treatment were instituted within the first eight hours. After excision reduction was carried out, often under the *x*-ray screen. After eight hours we employed surgical cleansing and enlargement to facilitate drainage—that is, "débridement" in the modern sense (see Morrison, 1940a, 1940b; Mackenzie, 1940: Bailey, 1940: d'Offay, 1940).

The removal of retained foreign bodies was incidental to the general cleansing of the wound. In early cases in good condition a careful search was undertaken, especially in the neighbourhood of joints, where, owing to constant movement, it was considered there was less chance than elsewhere of a retained fragment of projectile being walled off and rendered innocuous. Preliminary radiographs were essential, especially in cases presenting an entry wound and no exit wound, with the certainty of a retained projectile. All such cases should be sent, if possible, to places where *x*-ray facilities exist, and should not be explored "blind" first.

The multiple minute fragments of aircraft-cannon shell peppered over the skin and in the superficial tissues were left alone. We painted the puncture holes—sometimes as many as sixty or seventy—with iodine or gentian violet without applying dressings, as Bonnin (1940) suggests. Dressings, in fact, were best left off in such cases owing to their tendency to absorb the antiseptic dyes from the skin (Fleming, 1940).

Through-and-through bullet tracks caused by accidental discharge of firearms, without retained projectile, were often encountered. If not involving bone or large vessels we left them alone. It was astonishing how often these bullets missed or pushed aside important structures. In one case a 0.45 revolver bullet, entering just below the right fibular head, traversed the anterior compartment of the lower limb and came to rest overlying the first cuneiform, whence it was easily removed without fracturing any bone or damaging any nerve.

Tracer-bullet injuries were also seen. A pilot officer had his left humeral head shattered by a tracer bullet: the wound was still smoking furiously till completely excised. In such wounds the tissues around the bullet fragments were burned as well as torn. Extensive shattering injuries caused by fragments of high explosive from the German "Channel Charlies," with their potential risks of grave infection, were also seen.

We found the times for primary suture given by Jeffrey (1940) a useful guide. He states: "In the upper half of the body, including the arms, suture may be attempted up to twelve to fourteen hours after injury. In the lower limbs the limit should be six hours." We did not close up any wound, however, until it was completely excised. No muscle or tendon or nerve was sutured, the only catgut introduced being to ligate main vessels. The first part of the axillary artery was successfully ligated in one case to control a wound of the third part of the vessel. It was considered that prolonged hunting for a damaged nerve in a recent wound was inadvisable. Such cases when healed were sent to a neurological centre for secondary suture.

The wounds were lightly packed with acriflavine-paraffin gauze to prevent collections of blood in the depths and to act as drains. No wound was packed at all tightly, as it was found that tight packs elsewhere introduced into partially cleansed wounds to control haemorrhage as a first-aid measure invariably caused severe pain and inflammatory reaction and required removal in forty-eight hours.

The wounded limbs were then immobilized in plaster-of-Paris. Our technique followed well-recognized lines based on the improvements of the Winnett Orr treatment resulting from experience of surgeons in the Spanish War (Trueta, 1939: Jolly, 1940; Tudor Hart, 1939). No case was treated by Carrel-Dakin irrigation, which, though evidently still used in America (Hermann, 1940), is not employed in present war surgery. Wounds treated elsewhere, not immobilized, or inadequately immobilized on splints, were also put into plaster, with immediate cessation of discomfort, throbbing, and pain. Our plasters were skin-tight except in wounds left open and expected to ooze considerably. In these much cotton-wool was packed over the wound for the reception of discharges inside the plaster (Pannett, 1940). No "windows" were ever employed, the risk of window œdema being well known.

The patients were left undisturbed till the seventh to tenth day in soft-tissue injuries, and the fourteenth to twenty-first day in fractures, by which time the plaster had become loose and was no longer fulfilling its purpose of immobilization. Their progress was painless and afebrile. The plasters were then removed and packs and stitches taken out. A healing granulating wound covered by a variable quantity of thick pus and scabs was constantly observed, with no trace of active inflammation. The presence of dead tissue, as pointed out by Carrel and stressed in a recent paper by Riley (1940), had evidently acted as a stimulation to the proliferation of cells in the process of healing. The wounds were re-dressed, this time with merely a thin strip or wick leading into the wound cavity, easily capable of being extruded by the tissues. Superficial cutaneous irritation around some wounds yielded quickly to application of aqueous gentian violet. No septic lymphangitis or lymphadenitis was seen; no case had a secondary haemorrhage. The observation of Trueta and Barnes (1940), that immobilization in plaster minimizes lymph flow and therefore decreases the chances of absorption of bacteria and their toxic products, was confirmed.

Plaster immobilization was continued till the wound had healed completely. If not, the wounds and the limb inevitably became slightly painful and uncomfortable. Discomfort ceased at once on re-immobilization. No physiotherapeutic measures were started till the wounds had thoroughly healed.

Visceral and Facio-maxillary Wounds

Penetrating wounds of the abdomen and chest were also encountered. The importance of the "time-lag" in visceral lesions was well realized. The extensive intraperitoneal damage produced by projectiles entering through the buttock was again observed in our series. In one patient resection of four feet of small intestine in addition to suture of bladder and rectum was required, but, unlike Gordon Bell's successful case (Gordon-Taylor, 1939), this man died. The causal factor was the initial haemorrhage from the mesenteric vessels. In another case—a through-and-through wound of the right flank—a bruise of the lateral border of the ascending colon was the only visceral lesion, and was not extensive enough to require Jolly's (1940) reperitonizing operation.

Several facio-maxillary injuries were encountered. With a minimum of excision, displaced hard and soft tissues were sutured back as nearly as possible to the normal position, avoiding tension in the replaced structures.

Suturing was found essential, even at the expense of slight distortion, in order to control the very profuse and sometimes dangerous haemorrhage so common in these wounds.

The high frequency of abscess formation which supervenes in the lower jaw after such injuries (see Report on Maxillo-facial Injuries, 1939) rendered primary drainage advisable. In one case—a through-and-through wound shattering both superior maxillae and the nasal septum—a bilateral Caldwell-Luc operation was performed, on the advice of Major Cowper Tamplin, R.A.M.C., to facilitate drainage. The lessening of muco-purulent discharge from the traumatic facio-antral fistulae in this man (a German pilot sergeant), the evident improvement in the closure of the facial wounds, and the lessened risk of severe ectropion on the left side were gratifying. We had the co-operation of Lieut. C. L. Douglas, Army Dental Service, in the treatment of these cases, and they were transferred as soon as possible to a facio-maxillary centre.

Treatment of Burns

Fifteen burns came under our care. They were chiefly of the face and hands, of the first and second degrees, with small areas of third degree. We employed the immediate-coagulation method of combined tanning with silver nitrate 10%, tannic acid 10%, and gentian violet 1% aqueous solution, as described by Dennison (1939). Tannic acid has been used successfully, with various modifications in technique, in the present war (Cohen, 1940a; Gordon, 1940; Heggie and Heggie, 1940; Brown, Dennison, Ross, and Divine, 1940; Ross and Hulbert, 1940).

Thorough preliminary cleansing under anaesthesia was carried out first to eradicate the sepsis that is so likely to supervene and produce scarring and contractures even in burns of first and second degrees. It has been said that "wound excision as a general principle still stands as the surgeon's sheet anchor" (Max Page, 1940). Similarly, adequate preliminary cleansing is the sheet anchor of the treatment of burns.

After cleansing, the triple tan solutions were applied, and coagulation was accelerated by the use of an electric hair-drier. The tan was applied without any break in continuity over the flexor aspects of joints. A degree of splinting of the joints was therefore produced which was not considered unbeneficial, as the parts were placed temporarily in immobilization, the optimum state for healing of any wound. The supple coagulum of the triple tan proved far superior to the rigid eschar of tannic acid alone, and allowed gentle movements to take place without cracking. Movements of affected fingers were allowed from the seventh day onwards, any cracks appearing in the coagulum being filled by a reapplication of the tanning mixture. The pliability resulting from a thin application of the triple tan proved of special value in the treatment of burnt eyelids, whose essential mobility was thus maintained.

Oedema did not develop to any extent in our cases, the main factor in the oedema of burns—infection—having been controlled by the initial cleansing. What little oedema did appear cleared up on elevating the part on pillows. The absence of pain and sepsis was very noticeable. No necrosis of phalanges was seen, and there were no contracture scars. The results were uniformly satisfactory.

Chemotherapy

Chemotherapy was employed in only a few selected cases in our series of wounds and burns. Primary infections by haemolytic streptococci occur in only about 5% of cases with open wounds (Colebrook, 1940), and one of the few wounds we left accessible for investigation purposes—a penetrating abdominal wound—was sterile to culture on admission. Infection by streptococci more commonly occurs in hospital. The plaster immobilization technique minimizes this, for plaster cases militate against the ingress of haemolytic streptococci from the nasopharynx and hands of dressers (Hare, 1940).

Dealing with very recent wounds sustained in aerial combat and in an area where the soil is relatively "clean," we did not consider chemotherapy in any form an essential part of treatment. We employed sulphapyridine prophylactically—its most effective use, according to Buttle (1940)—in several large wounds in which complete wound toilet had not been possible and in which projectile fragments and devitalized muscle were still *in situ*. The dosage was two tablets (each 0.5 gramme) by mouth four-hourly for twenty-four hours, followed by 0.5 gramme four-hourly for the next forty-eight hours. The local application of sulphanilamide powder was not tried. None of our cases showed any streptococcal infection.

Sulphapyridine was given in massive doses in the one case which grew a culture of anaerobic organisms. This was a bomb-fragment injury of the right forearm, with broken ulna and sloughing flexor muscles, that reached us second-hand in an infected state. The benefit of chemotherapy was not noticeable, and amputation was eventually necessary.

All our cases had antitetanic serum either on or before admission, and no case of tetanus was seen.

Anaesthesia

Pentothal sodium followed by nitrous-oxide-and-oxygen administered by Boyle's apparatus has been used in almost all cases. The average British soldier has a phenomenal appetite for all anaesthetics. It was found that an average of 6 to 8 c.cm. of 5% solution was necessary for induction, and a satisfactory state of anaesthesia could not be obtained with less than 16 to 18 c.cm. This anaesthetic lasted for about twenty to thirty minutes, and the patient was round in under an hour. Some cases required about 30 c.cm. for half an hour's anaesthesia. These cases were not round for about two hours, and were drowsy for the remaining twenty-four hours. This confirms the findings of R. H. Moore (1940). When gas-and-oxygen was used as a supplement a smooth anaesthesia with good relaxation and a rapid recovery was obtained. For facial burns and injuries we used pentothal. It proved an ideal anaesthetic for all cases in which a clear airway could be maintained.

The R.A.F. fighter pilots were often brought into hospital in a highly excited state, and it took a great deal of gentle coaxing to persuade some of them to accept even a prick in the arm; any question of inhalation anaesthesia would have raised strong objections. It is now our custom to prescribe omnopon 1/3 grain and scopolamine 1/150 grain one hour beforehand. Phenobarbitone, 1 grain twice daily, is also prescribed for several days afterwards. Many patients have expressed the view that in the future they will not so much mind being wounded if they know that they will have such a pleasant anaesthetic.

In a few cases it was found necessary to operate before the patient had recovered from his shock, in order to arrest haemorrhage or, as in one case, to remove a burning tracer bullet. In these cases pentothal administered slowly gave satisfactory results. As in many instances the patient was already receiving intravenous saline, the pentothal sodium was added to it in the ward, and the patient fell asleep without even knowing that the administration of the anaesthetic had begun. The Army pattern transfusion set was used, 1 gramme of pentothal being added to 200 c.cm. of glucose-saline. The solution was run in at about 120 drops a minute until unconscious-

ness was produced, and then continued at about 40 drops a minute for the duration of the operation, the rate being increased or reduced according to the individual circumstances.

Severely shocked patients were not touched at the end of the operation, but when circumstances permitted were left on the table for several hours. We considered that lifting a gravely ill patient on and off the table, rolling him to put on bandages, and putting him into bed would have been almost certain to tip the balance in the wrong direction.

Local anaesthetics were never used in this series. Several cases admitted second-hand after having had wounds excised and explored for foreign bodies under local anaesthetics were found to be painful and infected. This unfavourable condition had been caused or aggravated in some measure by the insertion of a local anaesthetic into tissues potentially infected and certainly devitalized.

Summary and Conclusions

100 wounds caused by the projectiles of warfare, the majority of them recent, have been treated.

Excision in early cases, and débridement in later cases, followed by adequate immobilization in plaster-of-Paris, have been successfully employed.

Efficient immobilization lessens the incidence of infection in wounds and materially aids its resolution when once it has set in.

Chemotherapy is not necessary as a routine in the treatment of early wounds occurring in areas where the soil is not heavily contaminated with anaerobic organisms. Its best use is as a prophylactic agent in large wounds which it has not been possible to clean completely. We agree with the suggestion of a Field Ambulance officer, Lieut. E. S. Watson, R.A.M.C., that it should be employed as a first-aid measure at the same time as antitetanic serum is given to wounded men for whom adequate surgical excision may not be available for many hours.

The silver-nitrate–tannic-acid–gentian-violet treatment of burns again proved successful. We endorse the defence of tannic acid by Park (1940) and the opinions expressed in Cohen's (1940b) summary.

Pentothal intravenously has proved a safe and satisfactory agent for routine use in war surgery.

The use of local anaesthesia in the treatment of war wounds is strongly deprecated.

We wish to thank Major H. G. Hobson, R.A.M.C., for invaluable aid and criticism, and for permission to record our findings. We are also indebted to Lieut. W. Carton Winterbottom, R.A.M.C., who co-operated with us in the administration of many of the anaesthetics in these cases.

A SIMPLE METHOD OF ESTIMATING PROTHROMBIN IN CAPILLARY BLOOD

BY

JAMES INNES, M.B., Ch.B., M.R.C.P.Ed.

AND

L. S. P. DAVIDSON, B.A., M.D., F.R.C.P., F.R.C.P.Ed.

(*From the Department of Medicine, University of Edinburgh*)

The estimation of the prothrombin content of the blood is recognized as a necessary step in the investigation of the haemorrhagic states in general, and it is of particular value in cases of obstructive jaundice prior to operation and in haemorrhagic diseases of the newborn. The method described by Quick (1938) is usually employed. This entails the withdrawal of 4.5 c.cm. of blood either from a vein, which may be difficult to locate in obese or collapsed adult patients, or from the anterior fontanelle in infants, a procedure which the clinician may be unwilling to undertake in view of the haemorrhagic tendency.

If the prothrombin in capillary blood could be estimated in a simple and satisfactory manner the scope and application of such an investigation would obviously be extended. The following method, employing capillary whole blood and snake venom as a source of thromboplastic kinase, can be performed in a few minutes. We have carried out this test on a large series of normal persons, newborn infants, and patients with obstructive jaundice and liver damage, and have found that it gives results comparable to those obtained by Quick's and other methods.

Method and Materials

A standard white-blood-cell-counting pipette is used to measure the various ingredients. It is better to have a number of such pipettes, but if only one is employed it must be cleaned thoroughly with saline after measuring each ingredient. A solution of crystalline sodium oxalate (13.4 grammes per litre) is drawn up into the pipette, and a quantity equal to one division of the pipette is blown into a clean watch-glass. The skin is punctured so that the blood flows freely without squeezing. In infants the heel is the most suitable site. Blood is drawn up to the ninth division and then transferred to the watch-glass. Thorough mixing of blood and oxalate solution is effected by means of a small glass stirring-rod. The snake venom used is Russell-viper venom, supplied by Burroughs Wellcome and Co. under the name of stypven. The solution is prepared by adding 1 c.cm. of distilled water to 0.1 mg. of the venom in dry form. A freshly prepared solution is best, as the efficacy of the venom in solution decreases after a few days. Stypven solution and a solution of anhydrous calcium chloride (2.775 grammes per litre) are in turn sucked up into the pipette to the tenth division and are mixed with the oxalated blood in the watch-glass. Following the addition of the calcium chloride solution, visible fibrin formation usually occurs within twenty-five to thirty-five seconds as timed with a stop-watch. The change is best seen against a white background. The test is repeated on a normal person at the same time and under the same environmental conditions,

and the prothrombin index of the patient's blood is expressed as a percentage of this normal, as follows:

$$\text{Prothrombin index} = \frac{\text{Normal prothrombin time}}{\text{Patient's prothrombin time}} \times 100$$

With practice a high degree of accuracy can be obtained in assessing the coagulation time. Thus repeated estimations done on the same individual under standard conditions show a deviation of only one or two seconds.

It has been shown by Quick (1938) and by Fullerton (1940) that a marked lengthening of the coagulation time occurs only when the level of the prothrombin in the blood falls to 20% of normal or less. By diluting the blood of both the patient and the control to 20% with normal saline, minor differences in the coagulation time become more apparent. If it is desired to adapt this modification to the present technique, a quantity of normal saline equal to forty divisions of the white-cell pipette are added to the ten divisions of oxalated blood present in the watch-glass. After mixing thoroughly, a quantity of this mixture equal to ten divisions is transferred to a second clean watch-glass, in which the test is completed. It should be noted that the effect of such dilution makes it somewhat more difficult to see the onset of fibrin formation.

Comparison with Kato's Test

Our attention has recently been drawn to a paper by Kato (1940) in which he describes a test for estimating prothrombin using capillary whole blood. He states that many hundreds of such tests have yielded results comparable to those obtained by Quick's method on venous blood. The differences between the method described here and Kato's technique are as follows:

1. The use of a white-blood-cell-counting pipette obviates the need for obtaining the special microhaemopipette designed by Kato (1938).

2. The use of snake venom as a source of thrombokinase as described by Fullerton (1940) eliminates the necessity for preparing a brain extract as used by Kato

3. The carrying out of the test on a normal control person at the same time and under the same environmental conditions is felt by us to be a fundamental part of the method. In Kato's method no control on normal blood is done, reliance being placed on standardizing the solution of thromboplastin so as to produce a clotting time of approximately twenty seconds. The control eliminates the effect of minor variations in the solutions used and the changes in the clotting time which result from variations in temperature and humidity. In practice we use our own blood as a control, and have found that the clotting time of undiluted normal blood may be as short as twenty to twenty-five seconds in the heated nursery of the maternity pavilion and as long as thirty-five to forty-five seconds in the cooler general hospital wards in winter-time.

One of us (J. I.) was in receipt of the McCosh Bursary and Crichton Scholarship in Medicine during the period of this investigation.

Dr. Albert B. Sabin and Dr. Joel Warren (*Science*, 1940, **92**, 536) point out that the toxicity of most available gold compounds is perhaps the greatest barrier to their more widespread use in the treatment of rheumatoid arthritis. In their search for a compound which does not possess this danger of toxicity they have found in preliminary experiments on mice that calcium aurothiomalate fulfils this desideratum. Whether this compound is equally harmless to human beings has yet to be determined by clinical trials.

MULE-SPINNER'S CANCER

BY

E. M. BROCKBANK, M.D., F.R.C.P.

As a medical referee for industrial diseases I have se over 150 mule-spinners with epithelioma of the skin doubtful, early curable, and hopelessly neglected stat Visits to cotton mills, conversations with several hundr men and women spinners over 50 years of age whom have examined for pensions, and many talks with er ployers and representatives of the workers' Associatio have given me some practical knowledge of cotto spinning. Frequent visits to the Manchester Canc Research Laboratories kept me informed on the exper mental side of the problem. With such exceptional oppo tunities for doing so, I have formed certain conclusions o the causes of the disease and on measures which,

A mule-spinner at work.

systematically adopted by masters and men for its prevention or early recognition and treatment, would greatly diminish its dangers if not avert its onset altogether.

Incidence of the Disease.—Southam and Wilson in 1922 drew attention to the frequent occurrence of the disease, and the numbers of cases notified since then to the Medical Inspector of Factories have been recorded in his Annual Reports from 1923. During the seventeen years ending 1939 its average annual incidence was 64 cases with 21 deaths. In 1939 there were 52 cases with 20 deaths, and as medical referee I saw 16 cases last year. The continuing incidence of a preventable disease is very disappointing

Seat of Election of Scrotal Cancer

Mule-spinners work in bare feet on a wooden floor saturated with oil. They are constantly walking to and fro along the front of the machine, leaning well over but not actually against its front bar, whilst the carriage is moving outwards towards them, in order to join up very rapidly, piece, broken ends of the yarn. This is almost invariably done with the thumb and finger of the left hand. In most men the bar is on a level with the pubis and groins, and above the scrotum. In the hot room the spinners, in addi

and overalls only, perspire freely, and this must tend to wash off the natural grease of the skin and allow the oil to get on it.

Over 80% of cases occur on the left side. This may be due to one or more of the following causes:

1. The left side hangs anatomically lower than the right. This will be more pronounced when the spinner, in bending forward to piece with his left hand, stands on the left leg, sometimes on his toes, and balances with the right shoulder well above the left. The pelvis is correspondingly tilted.

2. Perspiration from the lower part of the abdomen may therefore tend to run down the left side of the scrotum more than the right.

3. The left side and, less often, the middle of the scrotum will come in contact with the left thigh and the oily trousers some hundreds of times a day.

Piecing with the right hand may, in the same way, be the cause of the trouble on the right side.

Mineral Oil as a Cause of Skin Cancer

Mineral oil was known in the middle of the last century to be a cause of epithelioma of the skin in the paraffin and shale-oil industry. The first case in a mule-spinner was found in the Manchester Hospital records in 1887, thirty-five years after the introduction of shale oil for lubrication of cotton machinery (Henry, 1926). It was proved in 1922 to cause the disease when painted on the skin of mice (Leitch, 1922), and many observations since then have shown that oils from certain fields of origin are more carcinogenic than those from other sources.

Oil on the Clothes.—The spinner oils the spindles twice a day, and these, revolving many thousands of times a minute, throw off some oil on to the clothes in the earlier moments after starting. A little will get on the hands when the oil-can is used and refilled twice a day, and will probably be wiped off on the clothes about the hips to clean the fingers for piecing. In some mills a special attachment to the machine reduces the need for oiling the spindles to once a week. A heavier oil is used twice daily on the carriage and wheels of the mule, and there is a general weekly overhaul and cleaning. More oil will then get on the hands, arms, and clothes, and the face is quite likely to have a little smeared on it unintentionally during all this work. Dermatitis of the face produced by dust or liquids not uncommonly arises in this way.

Oil in the Atmosphere.—Dr. E. L. Middleton (1926) found a definite amount of oil in a fine state of division in the atmosphere of the mule-room, and the hotter the room and the nearer to the machine the more there is. Some of this oil will get on the face and bare arms of the mule-spinners. There was less oil in the rooms where the earlier processes for mule-spinning are carried out, and very little or none in the air of the rooms of a ring-spinning mill. The preliminary processes of all spinning are carried out in hot rooms; but the men wear more clothes about the groins and are not in such constant movement about their work, with tilting of the body and pull on the trousers, as mule-spinners are. They come into daily contact with mineral oils, but do not often suffer from epithelioma of the skin generally or of the scrotum in particular.

Heat and Perspiration.—These alone will not cause the disease. Coal-miners are remarkably free from it, and yet in some hot pits they work in shorts and clogs and perspire freely. Coal dust, unlike its combustion-product soot, does not contain tar, and is not itself a cancer-producing irritant to the skin. In the shale oil and paraffin industry work is carried out in the open—in some processes in very cold temperatures, even as low as zero—and perspiration is not excessive. Both these substances, however, are much more carcinogenic than the mineral oils now in use in the cotton trade, and probably need no contributory cause in producing the disease.

Friction of Clothes.—Dr. Robertson (1927), medical officer of health for Darwen, in 1926 endeavoured by very careful practical investigation to prove that scrotal cancer was caused by friction on the scrotum by the upward pull of the overalls or braces during the piecing movements of the body. The disease is unknown in the woollen industry, in which spinners piece with both hands at once without any tilt of the body. His observations were also directed to prove that very little, if any, oil was thrown from the rotating spindles, but he agreed that some got on the clothes during the general oiling of the machines. Dyes or stiffening materials that may be in overalls are in his opinion a source of irritation, but these will be removed in their early washings.

Ichthyosis.—After an examination of 400 spinners, L. Savatard formed the opinion that ichthyosis is an important aetiological factor in the causation of mule-spinner's cancer.

Want of Bodily-Cleanliness.—Some managers of mills who have given close attention to the subject are of the opinion that neglect of soap-and-water cleanliness is a definite factor in causation.

Skin Protectives.—The sebaceous-gland secretion is protective against the action of a mineral oil, and, in control mice, if washed off with soap and water before painting with oil epithelioma will develop more readily than in the unwashed skin. A mixture of lanolin and olive oil applied to the unwashed skin before the application of mineral oil prevents the development of dermatitis and epithelioma. This observation led Dr. Alexander Scott in 1930 to try such an ointment to protect the shale and paraffin workers in Scotland from dermatitis and epithelioma of the skin, to which they are very liable. He informs me that the protection it afforded has proved so satisfactory that a proprietary preparation for the same object is still regularly used by the men. A similar preparation is applied daily in other industries as a preventive of dermatitis due to dust or liquids. These proprietary substances are preferred because they are easier to wash off than a grease like lanolin. Protective application for the thousands of spinners in cotton mills is not practicable, but it could be adopted by those over 50 years of age or those with specially dry skins, of whom there are comparatively few at work.

Conclusions as to Causation

1. *The primary cause* of epithelioma of the skin in mule-spinners is undoubtedly mineral oil.

2. A predisposing cause is probably an abnormally dry skin, especially in older men.

3. Excessive perspiration, by washing off the natural protective grease, allows oil close access to the skin. This is especially likely to happen on the scrotum.

4. Irritation may arise from friction of trousers or overalls on the scrotum during the movements of the body for piecing broken ends some thousand times a day.

5. Want of reasonable use of soap and water may be an occasional cause.

Protective Measures

Regular periodical examination of spinners should be carried out by a medical man for the earliest appearance of an epithelioma, which may be merely a local ichthyotic thickening of the skin or like a simple papilloma or wart. A microscopical examination is often necessary to settle its exact nature. Any one of these early changes can be excised or be treated with radium or *x* rays with such

The advantages of this method are as follows: (1) the treatment is non-odorous, non-greasy, and non-messy; (2) the bed-clothes or underclothes are not stained; (3) it is not expensive—each case costs about a penny for a course of treatment; (4) treatment is standardized at two days' duration; (5) it dispenses with the trouble of having clothes disinfected, thereby avoiding hospital treatment; (6) recurrences are few; (7) supervision is unnecessary; (8) baths are unnecessary.

The disadvantage of the method is that some patients complain of a burning sensation in the region of the scrotum and penis after four or five applications. Three or four days after starting the treatment there may be a very mild excoriation of the affected area, particularly the scrotum, and a scaling and slight exudation of serum may appear. This, however, does not incapacitate the patient, and within a week it usually disappears without treatment. The complication is probably due to the strength of the solution. Since using a half-strength solution on a new series of cases the excoriation has been observed in a very much milder form in only 3 cases out of 50. This development was seen in 8 cases in Class A, 15 cases in Class B, and 12 cases in Class C. In spite of this complication patients frequently make such remarks as: "The best night's sleep for a fortnight"; "This should have been used years ago" (this patient was treated three times previously with sulphur ointment); and "Good stuff, this: it does stop the itching."

I should like to express my thanks to Lieut.-Colonel J. F. W. Meenan, R.A.M.C., whose patience and kindly encouragement have contributed towards the completion of the above investigations. To Lance-Corporal A. Murdoch, R.A.M.C., my gratitude is due for his careful help, which has greatly assisted me in compiling these results.

SUBCUTANEOUS LIGATURE OF VARICOSE VEINS

BY

H. S. RUSSELL, M.D., B.Sc.

The ability to treat varicose veins by injection of sclerosing solutions is now an accepted part of a practitioner's therapeutic equipment. Unfortunately there are many cases which need something more drastic than injection alone. A positive Trendelenburg sign usually means that ligature of the saphenous vein will be required, either in the thigh or at the saphenous opening.

The methods described by recent writers are not applicable widely enough, as they require the use of an operating heatre, and many patients are unable to stay away from their work in order to attend hospital. For some time I have been trying to evolve a technique which would allow ligature of a varicose vein to be performed with a minimum of complication in the consulting-room. The method now used will be described.

Method of Ligature

The instruments required are one 2-c.cm. syringe, one perineal needle, strong silk or silkworm-gut, 2% novocain solution, and sclerosing solution as preferred (5% sodium morrhuate solution in my own case). The patient usually sits, but occasionally a standing position allows the vein to be found more easily. At the highest point where the vein can be clearly defined the skin is prepared and an intradermal injection of 0.2 c.cm. of novocain is made on each side of the vein. The wheals should be one to one and a half inches apart. The perineum needle threaded with silkworm-gut is now passed through one wheal, under the vein, and out through the other wheal. In some of the early cases the vein was accidentally transfixed, but this appears to be of little consequence apart from the bruising that results. If this mishap is suspected the needle should be left in position until the rest of the treatment has been completed. Transfixion of the vein can be easily avoided by inserting the needle for an inch or so in a direction parallel to that of the vein, and then changing the direction across the course of the vein. The suture is drawn through and the ends are left loose.

A sclerosing injection is now made at the level of the suture, the ends of which are then tied firmly over a tightly rolled pad of gauze. In the earlier cases rubber tubing was used instead of gauze, but the increased elasticity caused the ligature to cut through the skin and leave a scar. A strip of elastoplast is applied over the gauze pad. The whole operation takes about two minutes to complete. The veins below the ligature require injection also, but quite small amounts of sclerosing solution will suffice, as the downward current of blood has been checked. These additional injections can be left over until the stitch is removed, which is done on the fourth day.

After tying the ligature it is pleasing to demonstrate that the vein is now empty. This can be done by getting the patient to contract and relax his calf muscle several times or, more simply, by "milking" the vein downwards. The demonstration is quite effective if the case is a suitable one for the method.

Results

The first case was treated eighteen months ago and the result is still good. Most of the patients have been able to work during the period of treatment. They are well pleased with the result, and there is no scar. Out of a total of nearly 30 patients 3 have returned later to have the other leg treated in the same way. The majority of the patients had either been refused injection treatment elsewhere because of the large size of their veins or had been treated unsuccessfully. It should be more generally recognized that injecting sclerosing solution into a vein which contains blood under pressure will not cure the condition, and may produce an area of pigmentation, thus bringing the whole method into disrepute.

There was one partial failure in the series. In this case I could not define the vein above the knee and had to tie it at a point where venous pressure was fairly high. The vein became patent again in a few weeks, though in the interval large veins below the point of ligature were successfully sclerosed. This man had previously had his leg treated at several hospitals and is pleased with the result, but I regard it as a failure. He ought to have had the Trendelenburg operation.

The most satisfactory case was that of a woman aged 40, who had had bilateral varicose veins for twenty years. They were rather larger in diameter than the average thumb, and extended to the middle of the thigh. Subcutaneous ligature in both thighs and half a dozen injections have produced a perfect cosmetic result. After six months there are still a few tender nodules at the sites of large varicose dilatations, but her ulcer has healed, her legs look normal, and she can walk as far as she likes without trouble.

Complications.—One ulcer developed at the site of ligature. In this case the patient did not attend as instructed

for removal of his ligature, but allowed it to remain *in situ* for a fortnight. Where very large veins are tied a certain amount of periphlebitis occurs. I have seen no harm come of it, and an elastoplast bandage gives complete relief.

Summary

A simple and effective method of ligaturing varicose veins is described. No special apparatus or facilities are required, and no scar is produced.

Clinical Memoranda

Acute Crush Injury of Leg

In the case here reported there were delayed symptoms suggesting traumatic thrombophlebitis, followed by shock and, later, by renal insufficiency. It was successfully treated at the patient's home by four "elastoplast" bandages and two crêpe bandages.

CASE HISTORY

An A.F.S. man aged 41 was driving a motor-cycle combination while looking for incendiary bombs when he was suddenly struck by the off-side wing of a car driven by another A.F.S. man on similar duty. The former was wearing thigh-length rubberized gaiters, long stockings, socks, and strong boots. The inner side of his knee broke the gear lever and deeply indented the petrol tank. The inner side of his leg was crushed against the engine, and his boot broke the starting handle. He was taken to the casualty department of a hospital, but was sent home because he felt fairly well and had only a few abrasions.

First Day.—He complained of shooting pains extending from the inner side of the right ankle to the upper limit of the internal saphenous vein, a feeling of great heaviness, and a burning sensation on the surface of the skin. There was also numbness like that of a swollen finger when its base has been constricted. He was beginning to suffer from shock; his pulse was 120. There was gravitational staining of the skin of the thigh and buttock very much like the post-mortem variety. The leg was twice the circumference of the other and pitted on pressure. The skin below the knee was tense, glazed, and dull red. The posterior tibial veins had become superficial, enlarged, tortuous, tender, and firm as if thrombosis had occurred. This applied in lesser degree to the internal saphenous vein. There was a wheal 3 inches in length above the right knee, and a number of smaller ones, varying from 1/2 to 1¼ inches, on the inner side of the leg below the knee. Over these extended several superficial abrasions which had faintly yellow sloughing bases. The veins below the knee were in contact with the surface of the wheals, and through the latter, elsewhere lacerations in the superficial and deep fascia could be palpated, and dark blood could be pressed to the surface from injured muscle fibres and deep veins. The shock was treated, and hot Gamgee fomentations were applied hourly to the whole leg.

Second Day.—He had an anxious expression and had begun to vomit. The pulse was slow and full, and the little urine passed was dark brown and scanty. The fomentations had given the leg and abrasions a more healthy colour, but the limb was more tense. A little black blood had appeared on the Gamgee tissue. Wool was placed round the knee and ankle and an elastoplast bandage was applied from the toes to the knee and another, in continuity, to the upper limit of the saphenous vein. This was followed by two crêpe bandages, which were to be reapplied when they became slack.

Third Day.—There was a great improvement. The vomiting had ceased and there had been a larger flow of urine, which was of a much better colour. The circumference of the leg was considerably smaller, and two more elastoplast bandages were applied, followed by two crêpe bandages.

The patient was up in five weeks, when he complained of pain under the gluteus maximus. An elastic bandage was tried but proved uncomfortable, so the adhesive variety was again applied. A month later he returned to light duty wearing crêpe bandages.

Pathology.—The elastoplast bandages repaired the subcutaneous tears in the ilio-tibial band and the fascial planes, restored the normal circulation of the blood and lymphatics and through them the metabolic health of the muscles, and emptied and prevented the formation of pockets of blood clot whose autolysis under pressure and patchy necrosis were possibly responsible for the glomerular nephritis.

His legs had been healthy before the accident, and there was no family history of varicose veins. His weight had previously been stationary at 12 st. 7 lb.; two months after the accident it was 10 st. 2 lb.

Local Sulphanilamide for Penetrating Wounds of Joints

In view of the increasing use of local applications of sulphanilamide it may be of some interest to record the following cases of wounds involving the knee-joint.

Case 1.—A spinster aged 58 was admitted to hospital as an air-raid casualty with an extensive third-degree burn of the buttocks and a gross laceration of the right knee. She was very shocked, but improved after a blood transfusion. It was not until ten hours after admission that she was fit for operation: it was then found that an irregular wound six inches long on the inner side of the knee communicated with the interior of the joint through a deficiency in the capsule, two inches long, beneath the patella. The wound had been temporarily packed with flavine gauze, but was extremely dirty, containing brick dust and fragments of clothing. As much contaminated tissue as possible was excised, the wound was irrigated with flavine solution and packed liberally with sulphanilamide powder, and the skin was lightly sutured. The leg was placed in plaster. The burns were treated with tannic acid. The patient was ill for the next few days, and a course of sulphapyridine was given by mouth, after which she gradually improved. The plaster was removed after three weeks; the greater part of the wound had healed by first intention, and the remainder was granulating well. There had been only a slight discharge of inoffensive pus. There was a little movement of the joint. The wound was again dressed with sulphanilamide powder and the plaster renewed. The plaster was removed permanently after a further three weeks, and at the end of eight weeks the wound was quite healed and there was painless movement at the knee to 35 degrees. The burn was granulating and will need skin-grafting.

Case 2.—A child aged 6 was knocked down by a lorry and was admitted to hospital with a dirty lacerated wound nine inches long on the inner side of the right knee crossing to the lateral side in front of the patellar ligament. At operation it was apparent that a large flap of skin and superficial fascia had been raised and that there was a deficiency 2 cm. in diameter in the capsule of the knee-joint on the *lateral* side of the knee. The tissues contaminated with road dirt were excised as thoroughly as possible (this was unsatisfactory on account of the thinness of the flap) and the wound was packed with sulphanilamide powder and lightly sutured. The leg was placed in plaster after a small counter-incision had been made for drainage through the base of the skin flap on the outer side of the knee. Convalescence was uneventful, and when the plaster was removed seventeen days later the wound was found to be well healed. Four weeks after the accident there was a full range of painless movement in the knee, and the child walked and ran without a limp.

It is not always possible to excise all the contaminated tissue of a wound without making an excessive sacrifice of skin. In each case there was a penetrating wound of the knee-joint in a contaminated wound: in neither case was an effective débridement possible, and in neither case was there any evidence of infection developing in the joint. In the light of these and similar cases it seems that the topical application of sulphanilamide powder to dirty wounds marks a considerable advance in treatment, especially when combined with the well-established principles of surgical toilet and immobilization.

I am indebted to Mr. R. Ledge for permission to publish these cases.

Reviews

PRACTICAL OBSTETRICS

A Short Textbook of Midwifery. By G. F. Gibberd, M.B., M.S., F.R.C.S., F.R.C.O.G. Second edition. (Pp. 548; 194 illustrations. 18s.) London: J. and A. Churchill, Ltd. 1941.

The second edition of this book is sure of a warm welcome. It is no easy task to write a short textbook upon any branch of medicine, but the author appears to possess just those qualifications which are indispensable to success. He has complete command of his subject, including the latest advances; he can be at the same time both lucid and concise, but is never betrayed into prolixity; his choice of subjects for fuller exposition is barely open to criticism; and he does not fall into the error, common among "short" writers, of relying upon illustrations to amplify scanty textual descriptions. In short, Mr. Gibberd's book is an outstanding success. The undergraduate will be delighted because from it he can readily and pleasantly absorb nearly all that he requires for the ordeal of the examination table. The practitioner interested in midwifery but unable to devote much time to current periodical literature will be kept well abreast of the stream of obstetric progress.

Writers of short textbooks can seldom find space for full consideration of recondite subjects, but Mr. Gibberd has managed to slip in a detailed account of the toxaemias of pregnancy. The thoughtful independence which characterizes all his work is conspicuous in this section. In considering the aetiology of hyperemesis he comes to the conclusion that "it is caused by pregnancy; beyond that it would be imprudent to dogmatize." In regard to the whole group of conditions conventionally named "the toxaemias" he remarks that "they have two things in common—that is, they are peculiar to pregnant women and their aetiology is obscure." After this flat refusal to gratify the reader's natural desire for speculative elucidation he proceeds to give him something else to think about in the form of a close description of morbid anatomy and clinical phenomena. The story is completed by a practical and selective account of the more promising lines of treatment, during which the student will be able to relight his pipe. Although when discussing aetiology the author gives the impression of a wary traveller picking his way through a bog, when it comes to treatment he is on terra firma with a clear sky above. He is seldom in doubt as to the best line to take, and he makes it clear that what he recommends he has himself tested and tried out.

Another subject in which the author's personal interest is well known is that of puerperal infection, which receives the full consideration commensurate with its importance. Particularly useful is the discussion of chemotherapeutic methods of treatment. Knowledge of the risks attendant on the use of sulphur compounds has lagged far behind the enthusiasm created by the first stories of their success in the treatment of puerperal infections. These risks are fully explained, and the need for close observation of the condition of the blood is forcibly impressed upon the reader.

On the whole Mr. Gibberd has shown discriminating judgment in the utilization of his limited space. It is worthy of remark, however, that while he declines to describe the details of the Zondek-Aschheim and Friedman biological tests for pregnancy on the ground that "the details are unimportant to the clinician," he devotes several pages to the ingenious models which purport to "explain" the movement of internal rotation of the head. One is tempted to ask him, Does it matter a brass farthing to the clinician what causes this movement?

WORDS OF WISDOM

Practical Public Health Problems. By Sir William Savage, B.Sc., M.D. (Pp. 198. 10s. 6d.) London: J. and A. Churchill, Ltd. 1941.

When a county medical officer of wide experience decides, after putting off the major burden of his office, to utilize his comparative leisure by placing on record some of the views which have served him to direct his policy, we are as a matter of course respectfully interested. But when, for the purpose of these records, with the whole realm of public health to choose from, he elects to narrow down upon the field of environmental hygiene, we are at the first impression respectfully surprised as well. And yet on maturer reflection there may be reason enough. The subject is one upon which the opinions of an acknowledged expert are indeed of special importance at this time, for the modern medical officer of recent growth, by reason of his inevitable addiction to the social aspects of his work, is often too little informed regarding environmental hygiene, and would—or should—sincerely appreciate words of wisdom pronounced regarding it by one who can speak with high authority.

Such thoughts as these are suggested by reading the work entitled *Practical Public Health Problems,* in which many such problems are agreeably presented, ably discussed, and in the majority of cases most satisfactorily solved, by Sir William Savage. Here are some of the views which he expresses. In connexion with water supply he says that in shallow surface waters warmed by the sun a considerable coliform count does not necessarily imply danger to the consumer. He does not believe that sewage-contaminated streams, if drunk by cattle, can set up disease in them. Having himself conducted research upon effluents from creameries, he stresses their harmful effect upon river water, since milk and whey are each 150 times as detrimental as ordinary sewage. Referring to the examination of water samples he holds the opinion that it is always the business of the field worker to interpret the laboratory findings, and not to seek to devolve his responsibilities on a chemist or bacteriologist.

The author gives precise directions for disinfecting a cowshed after tuberculosis. He tells how to run a milk-pasteurization plant. He considers that the failure to sterilize utensils at dairies is the commonest factor in the production of high bacterial counts. To effect improvement in the bacterial standards of the milks supplied in a district a persistent drive against the worst offenders is, to his mind, the best plan. In the investigation of outbreaks of food poisoning, so soon as any source has come under suspicion he advises that the inspector should "race" unheralded to the premises, which may be a place of business, before the manager has had time to destroy the incriminatory evidence!

Other articles are those on food canning, housing inspection, and disinfection. They also are informative and carry conviction. The whole book will be found to possess a guiding value for medical officers as well as for sanitary inspectors, to all of whom it is cordially recommended.

ANXIETY AND ALCOHOLISM

Anxiety and its Treatment: with Special Reference to Alcoholism. By John Yerbury Dent. (Pp. 124. 3s. 6d. net.) London: John Murray. 1941.

Dr. Dent has some very sensible things to say about anxiety, especially in relation to alcoholism. His explanation of anxiety may be paraphrased thus. Every chan-

in a man's environment has to be met by some change in himself. The human machine maintains its precarious balance by two main reactions: attack or retreat. When the mechanism does not react as a whole in one of these ways there is friction and consequent inefficiency, or alternation of behaviour. This constitutes "anxiety." To be or not to be, that is the anxiety. Man's fore-brain, which is so much larger than that of any other animal, enables him to remember and to learn from experience. His hind-brain closely resembles that of other animals; its task is to react to stimuli, but the fore-brain inhibits this reaction while the nervous impulse is travelling through all the connexions that have been made by past experience. The hind-brain says "Leap," the fore-brain says "Look before you leap." Worry is only possible when there is a problem to be solved, a decision to be taken: it depends on the ability to see two sides of a question. Therefore man worries more than any other animal just because of his superior intelligence. A man who is considered well balanced has a satisfactory balance between his animal and human brains. Lack of such balance is apt to lead him to resort to a fore-brain sedative, but the more the fore-brain is drugged the more drug it requires. When anyone runs away from any discomfort the more acutely conscious he becomes of that discomfort. The alcoholic addict is one who does not face life without continual or intermittent resort to alcohol. He drinks to calm his anxiety, and a temporary relief is bought at no matter what price. Here we may remark in parenthesis that men and women are said to drink for different reasons: the man to convince himself he is a finer fellow than he is, and therefore he drinks in company; the woman to drown her self-pity, so she drinks in secret. Of recent years the "fine-fellow" complex has affected many younger women, but it remains true that all alcoholic addiction is an attempted escape from reality.

Dr. Dent is a convinced believer in the efficacy of treatment by apomorphine for alcoholic addiction. He adduces theoretical considerations and practical experience for his convictions, and gives full details of his treatment. On his own showing, however, the underlying psychological state will require attention after release from addiction, but with that he is less concerned in the present book. Nevertheless, he concludes with a very helpful chapter on "blitzkrieg nerves," and the whole work is interesting, practical, and, at the present moment, topical.

THE PROBLEM OF PAIN

The Problem of Pain. By C. S. Lewis, M.A., Fellow of Magdalen College, Oxford. (Pp. 148. 3s. 6d. net.) The Christian Challenge Series. London: The Centenary Press. 1941.

Mr. C. S. Lewis is rapidly acquiring a leading position among those writers who are trying to restate Christian dogma in modern terms—which is quite distinct from the "modernist" attitude. The problem of pain is of interest both to the medical man and to the theologian; they approach it, however, from very different standpoints. The former regards pain as something which it is his duty to relieve, the latter as something to be sublimated and reconciled with the conception of a benign omnipotence. Truth to tell, this book is more about the larger problem of evil in general, pain being regarded as the "only sterilized or disinfected evil," as distinct from intellectual evil or error. In the author's view pain is for the purpose of shattering our illusion of self-sufficiency, and his experience in the last war leads him to say, "I have seen great beauty of spirit in some who were great sufferers," while candidly admitting, "I have never for a moment been in a state of mind to which even the imagination of serious pain was less than intolerable."—Without depreciating in any way the deep sincerity and originality of thought which mark this book, as they do Mr. Lewis's other writings, we doubt whether it would be very helpful to the physician and his special problems. A brief appendix by Dr. Havard is much to the point, stressing the absence of after-effects from short, severe physical pain, compared with the deterioration of character which may result from long-continued pain. He concludes: "Pain provides an opportunity for heroism: the opportunity is seized with surprising frequency."

Notes on Books

A fifth edition of *Aids to Medical Diagnosis*, by the late Dr. A. J. WHITING and Dr. FREDERICK SUTTON, has been published by Baillière, Tindall and Cox at 4s. 6d. This book shows the characteristic virtues and vices of a certain type of registrar teaching. Its virtues are that it helps the student to organize his knowledge and write answers to examination questions; its vices, that it almost completely neglects the physiology and natural history of disease, and teaches from the textbook rather than the patient. We are prepared to believe that some students may be better able to pass their finals by classifying diseases of the heart into conditions in which the apex is, or is not, out, with or without superadded sounds, but it is not our idea of the proper approach to the cardiac patient. We note an excessive fondness for eponyms; few consulting physicians could define Nothnagel's syndrome, which is here mentioned, and few students are likely to meet it. There is a similar weakness for tabulated lists, but while the majority are almost pluperfect, there is a sly pleasure in finding that acute mononucleosis is missing from the differential diagnosis of diphtheria, and jaundice and prothrombin deficiency from the haemorrhagic states. It would be unfair, however, to bring heavy guns into action against this little cruiser. We can well imagine that the vade mecum will have its friends and that their gratitude will repay Dr. Sutton for the pains he has taken in rewriting it.

In our review of the first edition of Mr. LINDSAY REA'S *Neuro-ophthalmology* it was pointed out that the author had collected a mass of useful information that is not easily accessible in the systematized literature. The present edition (William Heinemann, 50s.) is a reprint of the previous edition with the addition of a hundred or so pages summarizing work published during the last few years: the additional material is arranged in chapters that are supplementary to those in the body of the text. As with the main text, the supplement shows the author's acquaintance with the scattered literature, but the matter is presented in a manner which is not conducive to a clear exposition. The present volume is still an uncritical summary of a wide literature and lacks conciseness and stress on fundamental conceptions. Its value as a guide to the literature is, however, considerable.

Volume lx of the *Transactions of the Ophthalmological Society of the United Kingdom* has been published by J. and A. Churchill, Ltd., at 30s. The main topics for discussion at the sixtieth session, held in London in April, 1940, were the choice of operation in glaucoma, the anatomy of the finer retinal vessels, diseases of the lacrimal apparatus, tarsectomy for trachoma; there were also a number of miscellaneous papers and descriptions of ophthalmological apparatus, and Mr. Montague Hine gave an account of some of the happenings and problems of the preceding six months as seen at an emergency ophthalmic base. The volume includes brief reports from those of the affiliated societies which were functioning in the first year of the war.

Materia Medica and Pharmacology for Nurses, by Mrs. GWENDOLEN HUGHES, M.Sc., gives a short and simple account of the subject. The author has managed to cover a very wide field in the short space of 160 pages and has maintained a very creditable standard of accuracy. The book is published at 4s. 6d. by Faber and Faber, Ltd.

Principal Drugs and their Uses, by A. L. MORTON (tenth edition, Faber and Faber, Ltd., 2s. 6d.), is a pocket volume intended for the use of nurses. All drugs in common employment are listed in alphabetical order and the composition and uses of each are stated in a few lines. Inspection of the volume shows that care has been taken to keep it up to date. The number of editions through which the book has passed proves that it meets a general need.

The seventh edition of JOSLIN'S book, *The Treatment of Diabetes Mellitus*, has been thoroughly revised and brings the subject right up to date—no easy task. A new section on hyperinsulinism is included. The book, though of less help in routine treatment, remains the best and most comprehensive reference work of books on the subject and must be on the bookshelf of all who work on diabetes. It is published by Kimpton at 35s.

Preparations and Appliances

EQUIPMENT OF A MOBILE UNIT

Dr. HAROLD C. J BALL, Medical Officer, Mobile Unit, New Milton, Hants, writes:

The equipment of the New Milton Mobile Unit not only incorporates one or two devices which have been described in the *Journal* during the last few months but also includes original apparatus for the administration at the site of an incident of radiant heat to patients suffering from shock. The following notes and especially the illustrations of radiant heat cradles may therefore be of interest to other medical officers of mobile units.

First, the general equipment—dressings, splints, instruments, anaesthetics, drugs, etc.—is contained in seven cupboards which are kept at the depot ready for action locally; they are easily packed into the mobile unit van within five minutes should our services be needed in an outlying district. Sterilized dressings are always in readiness in case local hospital or transport facilities fail. In addition we have a portable operating table which has been lent to us.

In our oxygen therapy apparatus we have copied that described by Dr. Marcus Bird in the *Journal* of September 21, 1940 (p. 387). The cost of this was negligible since we made use of copper tubing obtained from a car "dump" and quart milk bottles, and adapted old head-mirror bands and fittings for nasal administration. Besides four nasal attachments we have two old football bladders for use with gas masks, as suggested by Dr. H. L. Marriott (*Journal*, October 19, 1940, p. 519), all necessary pressure being controlled by gas taps. Stretchers in the unit are fitted with the inexpensive, light though rigid, support for a Fowler position which I described in the *Journal* of November 2 (p. 610).

For the treatment of patients suffering from shock we have designed radiant heat cradles which are illustrated (Figs. 1-4). Here again the outlay has been small, for they are each constructed of half-sections of a child's hoop and Essex boarding. The heat is supplied by electric lamps, or, alternatively, since electricity may fail in an emergency, from a primus stove; square and round biscuit and sweet tins and boxes of Essex boarding are used to connect the primus stove with each pair of cradles. Control of heat is regulated by sliding shutters and a central overhead outlet. The whole is easily moved to and from the stretchers; moreover, stretchers and cradles can be set up in the open by resting the stretchers on equipment cupboards or other available supports.

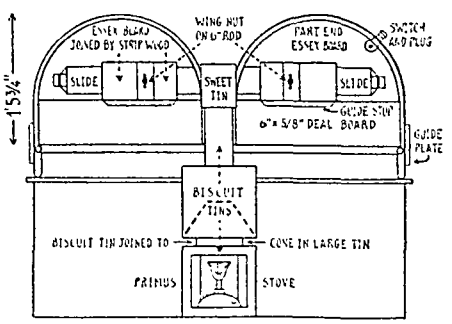

FIG 1.

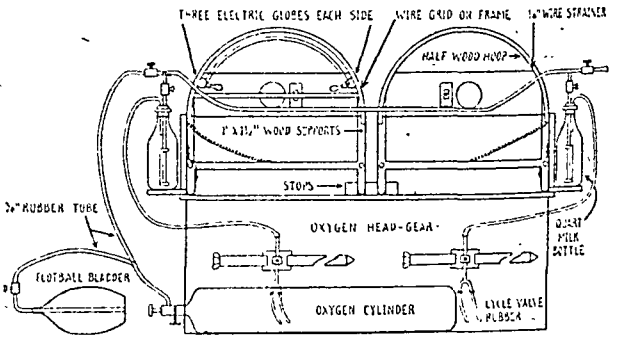

FIG. 2.

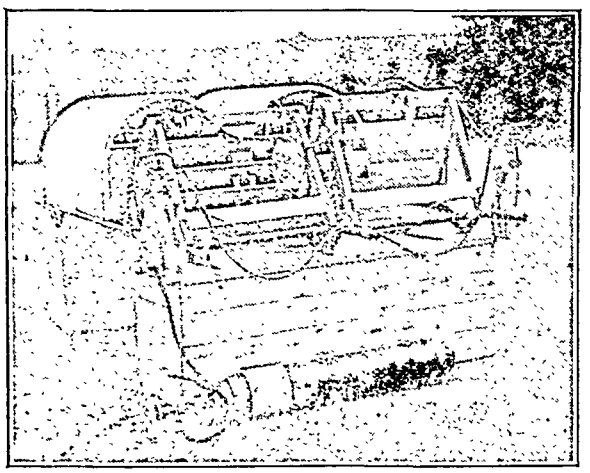

FIG. 3.

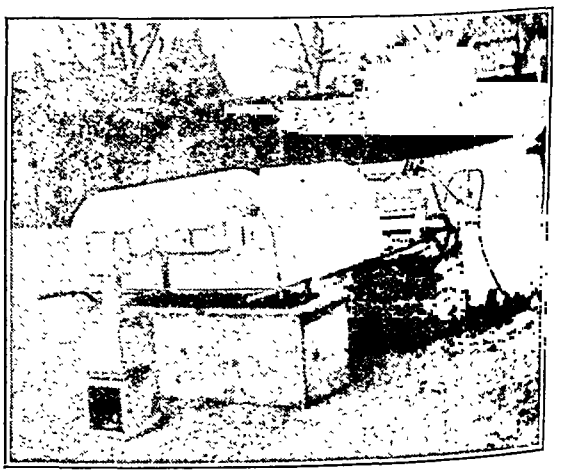

FIG. 4.

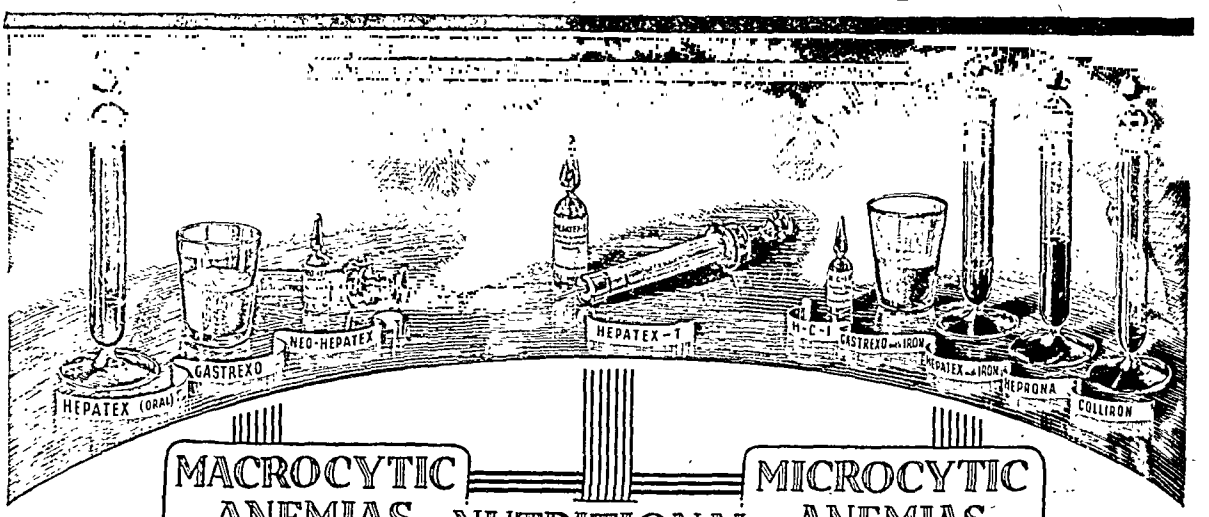
We are indebted to Mr. R. J. Stewart of the New Milton St. John Ambulance Brigade for making the cradles, oxygen therapy apparatus, and back rests to the stretchers.

SOME OF THE PRODUCTS OF

GLAXO LABORATORIES



A PAGE FOR YOUR REFERENCE

PRODUCT	DESCRIPTION	FORM
ANTIVIRIN *Antivirus preparations*	Prepared in jelly and liquid forms from cultures of streptococcus, staphylococcus and other organisms. The jelly is for use from the tube in easily accessible infections, the liquid for irrigation of deeper-seated lesions. In the treatment of boils, sinuses, abscesses, carbuncles running ear, infected wounds, etc., when direct contact between the lesion and the corresponding virus is obtainable, antivirus therapy is dramatically effective.	The jellies in large-nozzle or collapsible tubes, the liquid in 50 cc. bottles.
FLAVOGEL *Acriflavine Jelly*	Flavogel presents acriflavine (1 in 1 000) in a water-soluble jelly base smooth and soothing in action. Intimate contact between wound and tissue is achieved, with maximum bactericidal effect. For use on all wounds, whether infected or not. Flavogel does not cause pain, and minimises tendency of dressing to stick to the wound.	1½ oz. tubes, 16 oz. jars.
GLUCODIN *The reinforced Glucose*	GlucoDin, the original preparation of glucose, vitamin D and calcium glycerophosphate, has long been successful for the prevention and treatment of ketogenic disorders such as travel-sickness and fat-intolerance, and for providing immediate energy without taxing the digestion. GlucoDin replenishes glycogen reserves, supplies the carbohydrate essential to fat metabolism and helps to normalise calcium and phosphorus metabolism.	1 lb., 3 lb. and 7 lb. tins.
LEVU-CALCIN *Calcium Levulinate*	A sterile aqueous solution of calcium levulinate for parenteral use in all conditions needing urgent calcium therapy. The solution is stable. It has been used with marked success in pre- and post-operative treatment for preventing haemorrhage; inflammatory and allergic conditions with exudation; and hepatic insufficiency. For intra-venous or intra-muscular injection.	Boxes of 3 x 10 cc. (10%) & x 2 cc. (15%).
MINADEX *Mineral Vitamin Tonic*	An enjoyable reconstructive tonic, composed of three groups of therapeutic agents. Each fluid ounce contains: Ferri et Ammon. Cit. Vir. 15½ gr.; Mang. Glycerophosph. 1/25 gr.; Cupri. Sulph. 1/25 gr.; Calc. Glycerophosph. 2 gr.; Pot. Glycerophosph. 1·5 gr.; Sod. Glycerophosph. 1/10 gr.; Vitamin A, 13,000 I.U.; Vitamin D, 3,000 I.U.	6 oz. and 12 oz. bottles, and 60 oz. winchesters.
OSTERMILK *Successful Infant Food*	The successful dried milk food. The proportions of protein, carbohydrate and fat are carefully adjusted and standardised. The curd is light; extra vitamin D is added in stated quantity; the added iron content is three times that of milk. Ostermilk No. 1 is modified for the first three months. No. 2 full-cream is for the later months.	16 oz. tins.
SOLANTOIN *Anti-convulsant*	For the treatment of severe, inveterate, unresponsive epilepsy. Solantoin is the Glaxo preparation of the anti-convulsant sodium diphenylhydantoinate. Non-depressant. To be given alone or with a slightly dose of the usual anti-convulsant. Dose is one to three 0·1 gram tablets daily.	Bottles of 25, 100 and 500.
G.L. AMPOULES	The range of potent drugs available in G.L. ampoules covers a wide field. The ampoules have several advantages. They open quickly, cleanly and without splintering. A wide, smooth mouth is left for the entry of the syringe needle, and the ampoule stands firmly on its base. The prices are considerably below those usually prevailing.	Full list available on request.

GLAXO LABORATORIES LTD., GREENFORD, MIDDX. BYRon 3434

MEDICAL EVANS PRODUCTS

TREATMENT OF THE ANÆMIAS

MACROCYTIC ANEMIAS | NUTRITIONAL MACROCYTIC ANEMIAS | MICROCYTIC ANEMIAS

NEO-HEPATEX

A sterile solution of liver containing the maximum amount of the active hæmopoietic fraction. Each batch of Neo-Hepatex is clinically tested by independent workers and approved before issue.

Heo-Hepatex is painless on injection and can be given intravenously as well as intramuscularly.

Dosage.

Average uncomplicated case, 2 cc. on each of three successive days. Maintenance Dosage, 1 cc. weekly or less.

Issued in Ampoules and Rubber-capped Bottles.

HEPATEX (Oral)

A highly concentrated liver extract. Each teaspoonful contains the equivalent of two ounces of fresh liver.

Dose.

One to four teaspoonsful per day.

Issued in Bottles of 4-oz.

GASTREXO

A desiccated Hog's stomach preparation of high therapeutic activity and free from pathogenic organisms.

Dose.

30 grm. daily and gradually reduced according to progress.

Issued in Bottles of 4-oz., 8-oz. and 16-oz.

HEPATEX-T

A product in which all the known members of the vitamin B group present in liver, with the exception of nicotinic acid, are conserved. As nicotinic acid is eliminated during the process of manufacture 500 mgrm. per 100 cc. of pure synthetic nicotinic acid is added. Hepatex-T also contains the tropical anæmia factor. Each 2 cc. Hepatex-T contains 333 International Units vitamin B_1 and 10 mgrm. of nicotinic acid. Hepatex-T is painless on injection.

Dose.

Commence treatment with 2 cc. intramuscularly.

Issued in Ampoules and Rubber-capped Bottles.

Literature sent on application to Home Medical Dept., Hanover Street, Liverpool

HEPATEX COMPOUND INTRAMUSCULAR (H.C.I.)

A neutral, isotonic, non-irritant solution containing Neo-Hepatex, iron, arsenic, strychnine and sodium glycerophosphate.

Dose. One or two cc. daily.

Issued in Ampoules.

HEPATEX with IRON

A combination of Hepatex and Iron. Each fluid drachm contains the hæmopoietic principles of 2-oz. of fresh liver and one grain of metallic iron with a slight trace of copper.

Dose. One or two *fluid drachms* per day

Issued in Bottles of 2-oz.

HEPRONA

A tonic restorative indicated in secondary anæmia, convalescence and general debility in children and adults.

Heprona contains Hepatex, iron, glycerophosphates and vitamins B_1, B_2 and C.

Dose. Adults, two to four fluid drachms, once or twice daily. Children, one or two fluid drachms once or twice daily.

Issued in bottles of 6-oz. and 12-oz.

GASTREXO with IRON

A desiccated hog's stomach preparation, containing 3 per cent. of iron in a readily assimilable form.

Dose. 30 grm. daily and gradually reduced according to progress.

Issued in Bottles of 4-oz., 8-oz. and 16-oz.

COLLIRON

A colloidal solution containing 10 per cent. iron and adequate amounts of copper, manganese, and cobalt. Each drachm of colliron contains the equivalent of 32 grains iron and ammonium citrate or 12 Blaud Pills

Dose. According to type of case treated.

Issued in Bottles of 4-oz., 8-oz. and 16-oz.

SCOTLAND DESERVES BETTER SOCIAL LEGISLATION

There was a time when Scotland took a pride in the advanced state of her laws governing public welfare. Legislation often followed the English statutes on the same subject; it took advantage of the extra time to avoid some of their defects, and to introduce improvements which working experience had shown to be desirable. This was true of the Scottish Public Health Act of 1897, which derived its main features from the great English Act of 1875; and to a less extent of the Poor Law Act of 1845. In some aspects of social legislation Scotland took the lead from the start: one need only mention, by way of illustration, the lunacy laws of the middle of last century which in Scotland encouraged the admission to mental hospitals of voluntary and temporary patients without the stigma of certification. This benefit did not reach the English statute book till 1930. The Scottish Act of 1845 was more humane than the famous Poor Law (Amendment) Act of 1834, for it did not insist on the rigid "workhouse test." This piece of kindliness, which was no doubt in keeping with the Scottish tradition and the long association of poor relief with the kirk, had unfortunate consequences which could not have been foreseen at the time. Under Chadwick and his brethren the harsh "offer of the house" to persons applying for relief compelled the authorities to build workhouses. These in the course of time developed into hospitals, because they had to cater more and more for the chronic sick, the aged, and the infirm. The old mixed workhouse was a miserable thing, but progressive Boards of Guardians transformed many of them into institutions which could fairly compete with the voluntary hospitals in their neighbourhood.

When the Local Government Act, 1929, came into operation the new English authorities—the county and county borough councils—found themselves in possession of large numbers of Poor Law institutions. Some of these were ready-made first-line hospitals; others were capable of being enlarged, modernized, and "graded up" to form good hospitals at relatively little expense; and all but the worst had some value, because they could be used for a health purpose, such as the residential care of the chronic sick. In Scotland, unfortunately, few Poor Law institutions had been built at all, except in the larger towns, and fewer still were fit to be brought up to a reasonable hospital standard. For this reason the report of the Committee on Scottish Health Services had to confess in 1936 that there was a serious shortage of hospital beds in the country. "It militates against the ideal of early treatment," they reported, "and, in its effects among the working population, it causes much loss of working time and avoidable expenditure from insurance and other funds." In these circumstances it was to be expected that Scottish legislation would be quick to promote hospital construction and so redress the balance. But not so: although the committee recommended that a definite obligation should be placed on the local authorities to supplement existing hospital facilities if required by the central department to do so, little progress was made until war broke out. The evidence suggests that the fault did not lie with the local authorities but rather with the state of the law. However that may be, the outbreak of war disclosed such an acute shortage of hospital beds that the Department was obliged to build *ad hoc* hospitals for the reception of casualties.

Several factors have combined to retard the development of municipal hospitals in Scotland. The Scottish Local Government Act of 1929 was passed at the same time as its English brother, so Scotland lost its usual opportunity of profiting from the defects of the English statute; in fact, it introduced some faults of its own. A somewhat cumbrous section (27), corresponding with Section 5 of the English Act, enables local authorities to make a scheme for reorganizing their hospital facilities. As in England, the section has been little used, except in the cities. It is only a few weeks since the Corporation of Glasgow, apparently losing hope of more progressive legislation, took this first step in the removal of the institutional care of the sick from the Poor Law. Many authorities in England, however, were able to make use of a satisfactory alternative procedure to bring their institutions under public health administration, by the method of "appropriation"; this was already permissible under Section 95 of the Public Health Acts Amendment Act, 1907, and was extended to county councils by Section 163 of the Local Government Act, 1933. This important provision has been widely used in England, and under its aegis many public assistance institutions have become first-class hospitals.

If this were the only respect in which Scotland lags behind its neighbour in social legislation the position would not be so serious; but the English Public Health Act of 1936 gives large powers to local authorities to provide hospitals and allied services, including clinics and dispensaries, out-patient departments, maternity homes, laboratories, and ambulances. These admirable provisions have no counterpart in Scottish law, and Glasgow, in spite of its recent progress, is still under many disabilities. It has no authority to provide clinics apart from hospitals, and it is greatly hampered in the treatment of non-tuberculous crippling defects. The limitations are serious, and the remedy is simple. It may not be desirable at the moment to introduce an entire Public Health Act for Scotland, but surely the time has come when the two countries should be placed on an equal footing in the treatment of the sick and the crippled. The introduction of a few of the essential sections of the 1936 Act, with modifications to meet Scottish conditions, would not place a great strain on our legislators. Section 173, for example, which simplifies the provision for treatment and after-care of the tuberculous; Section 181, which empowers local authorities to provide hospital accommodation, including clinics, dispensaries, and out-patient departments; and Sections 196–8, with their commonsense powers to provide laboratories, ambulances, and post-

mortem rooms, were never more necessary than at the present time.

Scotland deserves better health legislation; if she is not allowed now to share equally with England she must inevitably suffer a severe handicap when the time comes for post-war reconstruction.

CARBOHYDRATES IN VARIOUS FOODS AND THEIR UTILIZATION

Until lately determination of the carbohydrate content of foodstuffs was in an imperfect state. The analytical methods were not of the best, and it is surprising that many writers on dietetics in health and disease were content to transcribe the values given by older workers. In this country the matter was taken up energetically by McCance and his colleagues, with the result that we have figures which are as reliable as modern analytical procedures can make them. In the U.S.A. the question is being examined again, and one or two recent papers are worthy of attention. Technical difficulties in obtaining reliable figures are considerable. Carbohydrates, for example of fruits and vegetables, have from the metabolic point of view been classified broadly as available and unavailable sources of energy. The available group includes the monosaccharides glucose and fructose, the disaccharide sucrose, and the polysaccharide starch. The unavailable group comprises hemicelluloses, cellulose, and lignin. Hemicelluloses comprise a group of polysaccharides, including pentosans, hexosans, pectins, uronic acids, etc., a large percentage of which can be hydrolysed to non-fermentable sugars. The chemistry of this group of substances is complicated. Cellulose is chemically a single substance and on hydrolysis gives glucose. Lignin (a complex substance of unknown composition) is contained in the supporting structure of plants and is present in small quantity in edible plants.

The analytical determination of the unavailable fraction is difficult, and the method described by Williams, Wicks, Bierman, and Olmsted[1] presents interesting features. They dried the macerated or sliced samples of fruit or vegetable in a hot-air oven at 60° C., pulverized the dried material, ether extracted and removed the soluble sugars (fructose, glucose, and sucrose) with 60% ethyl alcohol, and then estimated them iodometrically. The residue, consisting of starch and unavailable carbohydrate, was subjected to pancreatic digestion in buffered bile-salt solution at *p*H 8. This procedure converts the starch to maltose and renders the protein and fat non-interfering. The reducing power after yeast fermentation gives the figure for soluble hemicellulose. There remains an insoluble residue after pancreatic digestion which can be analysed into cellulose and water-insoluble hemicellulose. The values for available carbohydrate in the common fruits and vegetables thus found were very much of the same order as those given by McCance. The authors propose a classification of fruit and vegetables according to their carbohydrate content, but, as it was found that the older values for available carbohydrate were too high and for unavailable carbohydrate too low, there is much readjustment of the position of the individual foods. For those who still adhere to the prescriptions of diets for diabetics based on more or less accurate calculation of carbohydrate content it will be a source of satisfaction to see more fruits and vegetables in the lower-carbohydrate classes.

It was pointed out by McCance and his colleagues that cooking of certain foods leads to considerable losses in carbohydrate content, and that for such it is desirable to have figures for the foods as eaten. Carpenter,[2] in investigating the effect on carbohydrate metabolism of a variety of foods, carried out a comprehensive analysis of such things as rice, macaroni, potatoes, peas, parsnips, beets, carrots, various nuts, dates, and figs, with a view to determining water content, protein, fat, ash, carbohydrates (reducing sugars, disaccharides, starch, cellulose) in the conditions in which these foods were eaten (cooked or uncooked). The caloric values were determined in the oxy-calorimeter. Boiled rice, for example, can yield only 1 calorie per gramme, and white boiled potatoes rather less than this; boiled carrots or beets give only between 0.3 and 0.4 calorie per gramme. Nuts (high fatty content) of various kinds yielded from 7 to 9 calories per gramme, and dates and figs (very high proportion reducing sugars) nearly 3 calories. The available carbohydrate in various foods having been established, the effect of ingestion of a selected amount of each on the metabolism of a young healthy man was determined. The foods were given under basal conditions, so that what was really determined was the shift of metabolism from the particular basal levels of protein, fat, and carbohydrate to the new levels made possible by the availability of the constituents of the administered food. The constituent specially recorded was the carbohydrate, and the importance of the work lies in the demonstration that when the term "available carbohydrate" is used it should not be supposed that availability has any constant significance. First of all it was found that the mere ingestion of 250 c.cm. of water on three separate occasions raised the consumption of carbohydrate from basal levels of 7 to 11 grammes per three hours by as much as 6 grammes per three hours. It is not stated whether the water given was cold or hot, a point perhaps of some significance. As the amounts of the various articles of diet given in these experiments varied, comparable results for increased carbohydrate combustion were obtained by recalculating the latter for the case in which the amount of available carbohydrate would be 25 grammes. Applying this calculation, it was found that the rise in carbohydrate combustion during three hours for amounts of certain foods corresponding to 25 grammes available carbohydrate was no greater than would have been obtained with 250 c.cm. of water. Such foods were boiled rice, boiled macaroni, white raw potatoes, and nuts of various kinds. Boiled parsnips, beets, and carrots gave very marked increase in carbohydrate combustion in the three-hour period; white bread, dates, and figs gave increases of the same order. (It was found that, whereas raw carrots gave a greater rise than boiled carrots, the reverse was the case with white potatoes; this is perhaps explicable on mechanical grounds.) The time course of the rise in carbohydrate

[1] *J. Nutrit.*, 1940, **19**, 593

[2] *J. Nutrit.*, 1940, **19**, 415, 423.

combustion (determined at fifteen-minute intervals) showed that cane sugar or dates give a very sharp rise, but a rapid fall to pre-ingestion levels. Glucose gives a much smaller and less acute rise, but a higher level was maintained for a much longer time. Boiled beets, boiled parsnips, boiled and raw carrots, all combined large and acute increases with maintenance at elevated levels throughout the three hours of observation. Although the results obtained with these various foods are perhaps not unexpected, it is important that such experiments should be extended. The practitioner recommending a diet, most often qualitatively, should have a picture before him of availability of carbohydrate in foods based not only on the bare bones of chemical analysis but also on the actual availability to the organism when fed.

As to the so-called unavailable carbohydrates, the commonly held view has been that the human subject is unable to cope with them enzymatically and that their excretion is a matter for bowel action. But that in certain circumstances these unavailable carbohydrates can disappear from the alimentary tract is indicated by some recent work of Shepherd, Hummel, and Macy.[3] They point out that the digestibility or disappearance of fibre (that is, the part containing cellulose, hemicellulose, and lignin) from the digestive tract of man is very variable, and depends to some extent on its content of cellulose and hemicelluloses (lignin apparently not being digested at all) and upon the presence of bacteria in the alimentary tract. The authors studied the metabolism in children aged 5 to 8 years under controlled conditions for periods of thirty to fifty days. The daily diet was then altered. During the control periods the diet included 100 grammes of apple and 100 grammes of banana, or 200 grammes of apple only. During the experimental period 100 grammes of banana a day were added in one group; 100 grammes of banana were added and some bread and "cereal" removed in another; and in a third group 100 grammes of banana and a certain amount of potato, butter, and white bread were added. Adding banana to the diet increases its lignin content, and changes the quantities of both cellulose and hemicellulose in the gut; banana also increased the amount of pectin in the diet, and it is stated that this seems to have unique physiological value in stimulating better utilization and passage of intestinal contents, produces a more satisfactory buffer action, and effects a change in the bacterial flora in the faeces. The proportion of the cellulose and hemicelluloses in the diets was determined and an estimate made of the amount disappearing from the intestine. Thus of 112 mg. of cellulose per kilogramme of body weight in the control period of one group of children 81% disappeared, and of 119 mg. hemicellulose per kilogramme 63% disappeared. These percentages were maintained even after the daily addition of 100 grammes of banana. There was wide variation in the percentages disappearing in different individuals, and these are held to be characteristic and dependent upon the proportions of lignin, cellulose, and hemicellulose in the daily diet rather than upon the total amount of fibre ingested. Whether these very considerable disappearances of "unavailable" carbohydrate have any physiological significance is not clear, but the authors suggest that there may be a protein-sparing action and that the character of the fibre (that is, the ratio lignin:cellulose:hemicellulose) may have dietetic importance.

PHYSICAL MEDICINE, ORTHOPAEDICS, AND THE SERVICES

The field of activity claimed by those who practise physical medicine has been cursed by many cumbrous names; moreover, the subject is not "understanded of the people," and little comprehended by the profession at large. There are adequate reasons for this. First, the methods used by those who specialize in it do not form a real part of the training of students: secondly, the apparatus employed lends itself all too often to a blatant form of quackery, thus spreading disrepute far and wide. Then, again, the majority of these methods are available, through the medium of medical auxiliaries, to practitioners by merely sending the patient "for massage" or "for electrical treatment," leaving the choice of method and technique to the trained—but not medically trained—technician. When such treatment gives good results the practitioner is apt to infer that technical knowledge on his part is superfluous and that the help of an expert colleague is even less necessary. Poor results are blamed on the apparatus used—whether ultra-violet light, short wave, or mobilizing exercises—without regard to the possibility that the method that has proved unsatisfactory might never have been employed in that way if experienced medical supervision had been invoked.

As a corollary to these facts there has arisen some dissension between the specialist in physical medicine and the orthopaedic surgeon. Orthopaedic surgeons have been heard to claim that they are capable of seeing their cases through from beginning to end, and that unless they can do so their results are handicapped or even completely marred by the "interference" of the physical medicine specialist. The consultant in physical medicine for his part has been heard to say that the orthopaedic surgeon makes no attempt to evaluate, in close collaboration with him, other methods, and that he, the orthopaedic surgeon, has inadequate knowledge of the various means employed in physical medicine. This disagreement between the two branches is unnecessary and hinders progress. A glance over the field of those who practise physical medicine, whether in spas, by expert prescription of massage and medical exercises, by occupational therapy, or by the more direct physical methods of electrical currents, will make it clear that their work is the medical counterpart of the orthopaedic surgeon's. If consultants in physical medicine were regarded as "orthopaedic physicians" their field of activity would become clear, and their function in relation not only to orthopaedic surgeons but to the whole medical profession would drop into its proper place and perspective. Their advice, special knowledge, and collaboration could be sought without fear of trespass or overlap. It is satisfactory, therefore, to note that the Director-General of Army Medical Services has realized the importance of this branch of practice by the appointment of a Consultant in Physical Medicine with the rank of a higher consulting officer. The duties attaching to this new post go further than advising and helping in the physical treatment of injured soldiers and convalescents. The Director-General has, wisely, looked to the knowledge of function and movement possessed by this adviser to help and guide him in the conditioning of recruits, especially those with physical handicaps who are amenable to intelligent re-education and remedial exercises. The consultant and his chosen team are available to help those whose special duty

it is to train the recruit forward into fitness and hardness. Here indeed is a means for joint work in preventive medicine and one that should promote close and warm liaison between our profession and the commanders in the field. With such an organization in effective operation the orthopaedic surgeon could feel assured not only that his results will not be marred, but that they will be improved, thus freeing him from anxieties about the final stages of treatment and enabling him to concentrate upon the vast surgical problems that already face him.

It will be interesting to watch the fruits of the new appointment and of the policy behind it, and see whether the other Services follow the lead given by the Army. A point to look out for, when the time comes to assess results, is whether this new move has practical value in active war areas also, especially in places such as the Middle East, where problems of evacuation are difficult and every man returned to the firing line means so much saving of time and transport. The appointment of a Consultant in Physical Medicine to the Army, with a well-defined field of activity, means also the freeing of his branch of work from radiology, and this should be welcomed by the radiologist, to whom physical medicine is a secondary subject with which he does not claim to be fully conversant. The movement towards giving a status of its own to physical medicine is in harmony with the opinion of a special committee of the British Medical Association, whose final report was under review, in consultation with Lord Dawson's medical committee of the National Physical Fitness Council, when war broke out.

TREATMENT OF SEVERE DIPHTHERIA

The war has given a great stimulus to preventive medicine, and as a result of well-directed propaganda active immunization of children against diphtheria has been carried out on a larger scale than would have been expected in peacetime. But still more effort is needed, and we should not rest satisfied until over 75% of the child population is protected against an infection that takes an annual death toll of some three thousand lives. Early treatment is vital for those who are infected; it is almost axiomatic that patients do not die if given enough antitoxin within twenty-four hours of the onset of the disease. Yet every superintendent of an isolation hospital can tell of admissions two, three, or more days after the onset of illness—or, for that matter, well after the first visit of the doctor. Antitoxin is often of no avail in these late cases, especially in those in which the *gravis* bacillus is present. Dr. O'Meara[1,2] and Dr. McSweeney[3] think there may be an explanation, and, what is more, a way of improving this situation. O'Meara believes, on the evidence, that most or perhaps all commercial antitoxin has a low "avidity" for diphtheria poison—that is, when it meets and unites with the diphtheria toxin in the tissues of the patient the bond of union is not a firm one and may be quickly or easily dissolved, thus allowing ordinary toxin as well as other poisonous principles not hitherto recognized to spread and overwhelm vulnerable tissues. McSweeney obtained from the Wellcome Laboratories some special antitoxin of conspicuously high "avidity," which he tells us contained an unusual amount of antibody or antitoxin to the second poisonous principle postulated by O'Meara. With this antitoxin McSweeney treated sixteen patients suffering from severe diphtheria—Grades 3 and 4. The death rate for these two grades has been 25% in Dublin in the past; in McSweeney's group it was 6.2%. Unfortunately the figures are very small; an arithmetical calculation would seem to indicate that if successive groups of sixteen patients in Grades 3 and 4 were treated with ordinary antitoxin, about one in each twenty groups would yield fifteen recoveries. It is true that this argument does not cover the whole ground, for McSweeney out of his long experience says that he has never before seen patients in Grades 3 and 4 show such happy progress—absence of cardiovascular failure, rapid clearing of throat, absence of albuminuria, few paralytic sequels, rapid disappearance of bull-neck, and absence of failure of blood pressure. Obviously he and others will make every effort to treat many more patients with similar antitoxin. Here an unfortunate difficulty arises, for McSweeney states that the avid serum he used was not produced by any special methods of immunization, or by any alteration of inoculation of horses based on the use of O'Meara's second toxin. McSweeney informs us that avid serum cannot be produced at will and supplies are not obtainable. The papers will attract much attention, and we shall have to wait for confirmation by O'Meara and others that *gravis* cultures from many centres will produce in guinea-pigs the picture of hypertoxic diphtheria described by him and that this can be cured by avid antitoxin. If further trials repeat the results presented by McSweeney there will remain to be discovered a method of producing avid antitoxin.

EMERGENCY LIGHTING AND POWER FOR HOSPITALS

The need for an emergency electrical generating set in hospitals has been forcibly illustrated since the air attacks on large cities began. Even if a hospital is not itself damaged its work may be seriously hindered when the main supply is interrupted. Economical automatic devices for stand-by equipment for lighting only have been mentioned in these columns, but to supply both power and light to a large institution is a much bigger problem and necessarily more expensive than fitting up an alternative plant for the lighting of a first-aid post, an operating theatre, or a control room. A medical man who can speak with authority on this subject, having visited a great many hospitals in different parts of the country, informs us that only a few hospitals have emergency generating sets. There are examples on the South Coast and in the Midlands. In these the set was installed primarily to supply the *x*-ray services and was inspired by the radiologist in charge, but as events have turned out it proved to be to the benefit—in one instance the salvation—of the entire hospital. These hospitals were damaged and the mains supply cut off, but the temporary set did excellent work and enabled the hospital to carry on. The energy-generating set in one of them consists of a 20-h.p. paraffin engine driving a 10-kilowatt three-phase 400-volt generator through a flex belt drive running at 400 revolutions per minute. The engine exhaust is led into an old chimney stack, and the cooling is brought about by means of two 250-gallon tanks of water and a circulating pump. The mains cable-ends from the meter are diverted from busbars—by which is meant the conductors on a switchboard to and from which the various circuits run—to a tripole change-over switch, and one side is fed back to the busbars and the other to the emergency set. The total cost of this installation—the set itself having been bought second-hand for £300—including the tanks and switches and the expense of installation was £360. The test of the

equipment came on a night when the town was heavily raided. The emergency set was in operation within ten minutes and maintained the necessary lighting of the hospital and working of the lifts, as well as serving the x-ray mobile unit and other plant. During the raid the hospital itself caught fire, and over a hundred patients had to be evacuated, a task which was only made possible by the working of the lifts. Much valuable equipment was also moved from parts of the building on fire, including most of the x-ray and operating theatre equipment, and this again was only possible by the emergency lighting and power provided. On subsequent occasions the lights failed, and each time the emergency set stood up to a heavy night's work, and kept things going until the mains came on again, in one case not until forty-eight hours after the first interruption. The same hospital also suffered from damaged water mains, but on the day following the raid the boilers, which are fired by electrically operated mechanical stokers, were started and fed from reserve water, and a temporary water supply was provided for the hospital, which enabled emergency treatment and (gas also not being available) cooking by steam to be carried on. The laundry at this hospital is electrically driven, and half of this could be used while the mains supply was out of action. The cost of the installation may make a hospital board hesitate, but it might prove to be an economy in the case of hospitals in vulnerable areas.

WARTIME STREET LIGHTING

A most excellent report on "Fundamental Requirements underlying the Wartime Street Lighting," prepared for the Joint Committee of the Ministry of Home Security and the Illuminating Engineering Society, is summarized in a recent issue of the *British Journal of Ophthalmology*.[1] Note is made of the amazing range of human vision according to the lighting, from summer sunlight to faint starlight, a range of about one hundred millions to one. Dim light presents serious difficulties owing to the sudden movements of persons from brightly lighted rooms, from exposure to lights in the outdoor dimness, and because of the peculiar reactions of the healthy retina to dim light. Small objects cannot be seen with certainty and colour cannot be distinguished. The value of the dim street lighting of 0.0002 foot-candle depends entirely on the avoidance of factors apt to depress visual acuity. Change from lighted interiors to out-of-doors should be slow. Light-traps, besides their primary object of preventing escape of light from within, have a secondary field of utility in providing a period of adaptation. The next step is to avoid the presence of objects of undue brightness outdoors. Car headlights and traffic signals of a value exceeding the minimum for recognition inevitably give rise to some degree of glare. There seems good ground for the adoption of a value of brightness of the order of 0.05 to 0.1 equivalent foot-candle as a limit in streets. These limits have been independently determined with a view to restricting conspicuousness from the air. Lights on refuges and obstructions frequently offend by their glare, making it difficult to see outlines of adjacent objects. The Lighting Order on these lights is much higher than the proposed limit. Pedestrian torches offend because of the concentrated beam; a box with no lens giving a larger light area of low but even brightness would be much better. Stress is laid upon the high value of large-size white painting of obstructions, of walls and railings at crossings, of the vertical surfaces of kerbs, and the white paint on motor vehicles. All should have a greater area of whitening than now usual. This would give the eyes of passengers a better chance of seeing them. Isolated bright spots of light, such as luminous crosses on islands or rear lights of cars, make it almost impossible for the road-user to see what is beyond them. Experience has shown the high value of a uniform level of illumination with, so far as possible, no region of complete darkness. The measure of illumination provided by wartime street lighting, though so small, is of appreciable benefit, especially when applied on a wide scale. In this issue of the *Journal* is a paper by Mr. Bishop Harman on testing night vision. His plan of seeing groups of white disks and counting them is based upon the reaction of the normal retina to dim light. It may enable pedestrians to be sorted out—the relatively safe and the unsafe.

AMERICAN DOCTORS FOR BRITAIN

President Roosevelt's latest interpretation of the phrase "all aid for Britain" in his call for 1,000 American doctors to volunteer for service in the R.A.M.C. and the E.M.S. in response to an appeal from Sir Philip Chetwode, chairman of the British Red Cross Society, will hearten members of the profession in the country, wherever their work lies. As was pointed out in a leading article in these columns a fortnight ago (April 12, p. 509), the effect of the increasing demands of the Services and of the E.M.S. has been to deplete general practice to such an extent as to endanger the health services available to the civil population. The need for more medical men is a pressing one, and Sir Philip Chetwode in his appeal stated that up to 1,000 were "required to assist both the military and civilian medical services." American doctors under 40 years of age are asked to volunteer for service with the R.A.M.C. and those under 45 for the E.M.S. All will, of course, retain their American citizenship but will be accorded British registration as physicians and surgeons. The terms and conditions of service will be the same as those for their British colleagues, except that their pay will not be subject to British income tax. They will all be asked to serve for a minimum of one year. Mr. Norman H. Davis, chairman of the American Red Cross, in a statement issued in Washington on April 21, said that he was confident the response from the medical profession would be splendid and that many of those eligible would accept this opportunity for humanitarian service. The project has the approval of the President of the United States, the Secretary for War, and the Surgeons-General of the Army and Navy, as well as the Surgeon-General of the United States Public Health Service. In dealing with the applications the American Red Cross is to have the assistance of the Division of Medical Sciences of the National Research Council, the American Medical Association, the American College of Physicians, and the American College of Surgeons. At a Press conference in London this week Dr. J. E. Gordon, American liaison officer at the Ministry of Health, said he felt sure of the welcome that American doctors will receive from their British colleagues; and Mr. Ernest Brown, Minister of Health, in a message which was read by Sir Wilson Jameson, expressed the nation's thanks to Mr. Roosevelt for his "powerful support," and said that all those who joined us would receive a warm welcome and would form an integral part of our own services.

Prof. W. W. C. Topley, M.D., F.R.S., who holds the chair of bacteriology and immunology in the University of London at the London School of Hygiene and Tropical Medicine, has accepted the appointment of Secretary to the Agricultural Research Council.

TESTING NIGHT VISION

BY

N. BISHOP HARMAN, F.R.C.S.

"Test for Night Vision" is the title of a seven-page booklet[1] by Dr. W. D. Wright, lecturer in physics in the Imperial College of Science and Technology, which accompanies a test designed by him. Dr. Wright's experience as a physicist makes his consideration of the problem of night vision valuable. He writes:

"The ability to see in the dark varies from one individual to another. In normal times a test for night vision is of value as an indication of under-nourishment, as a means of measuring the development of certain visual diseases, and in connexion with scientific investigations on vision. In time of war it is important that all should know how well they can see in the dark, for both their own lives and, if they are motorists, those of other people may be at stake unless they adjust their activities in the black-out to suit their ability to see under these conditions."

There is no doubt of the truth of this statement. But in this country, at any rate up till now, experience has shown that ill nourishment has been of secondary influence in comparison with certain eye defects in diminishing the ability to see at night. But that does not affect the value of any test in these times.

Dr. Wright's apparatus is a simple one. At the ends of a baseboard measuring 8 in. by 6 in. are hinged two other boards which will stand upright. One is a support for the test cards; the other, on the side away from the patient's eyes, has a disk an inch in diameter covered with a luminous radium compound which gives a faint glow of light that serves to illuminate the test cards. These test cards are black. On each is one letter **C**, $4\frac{3}{16}$ in. in diameter and 5/8 in. in breadth of limb. These letters are of varying shades, from pure white to a dark grey that is almost black. There are nine grades. It is recommended that the person to be tested should remain in the dark for fifteen minutes. Then the cards are exposed to the radium glow and examined at a distance of 12 inches. The test lies in the ability to see the gap in the circle of the **C**; whether this is upwards, downwards, to the right or the left. Dr. Wright has tested some 300 persons: 49% could see No. 7; 20% No. 6; 6.5% No. 5; and about 1.5% the faintest, No. 9. Young persons see better than the older.

Practical examination of the test confirms these findings. But certain criticisms arise from this examination: (1) It is evident that the radium illumination may be variable. There can be nothing "standard" about it. (2) The hands of the examiner when shifting the cards are disturbing to the examinee; this is easily prevented by the use of black suede gloves. But worse than this is the fact that examination of the more difficult cards is hindered by a sheen from the smooth black of the cards and the baseboard. (3) The test is made at 12 inches, whereas long experience of eye men has shown that any standard vision test should not be at a less distance than 5 or 6 metres.

Some years ago I made a number of tests of the light sense of patients suspected of tobacco amblyopia. The fields of vision were mapped out in varying illumination. The method was found effective.[2] Since then I have tried other light tests. The aim has been to use a standard illumination and a test that would need a minimum of visual acuity or form sense. A standard candle—i.e., a candle burning 120 grains in an hour—is easily got, and it does not vary. By fitting this candle inside a box (somewhat like a child's toy magic lantern, but with no lenses, a wider "snout," and the inside painted dull black) we obtain a standard beam of light which will illuminate with a glow the usual Snellen test card from a distance. Since the letters on Snellen's test require both sight and knowledge of letters I used my revolving **E** test. (This was designed for use in infant classes. There is one **E** on each line, and each is mounted on a pivoted card so that it can be turned to any position. The child is told to look at the three fingers of the "hand" on the card, and put his own hand in the position of those fingers.)

When, in a dark room, the boxed-in candle-light is placed alongside the patient at a distance of 5 metres from the **E** test card, the light on the card is only 1/269 of a foot-candle. Yet a normal-sighted subject in the early thirties who could see 5/5 easily with the normally lighted test could see with the candle-glow 5/20 and occasionally 5/15.

In both tests—Dr. Wright's 12-inch **C** and the 5-metre **E** cards—it was noted that by a little legitimate dodging it was possible to get better vision than straightforward looking gave. If one looked a few inches away from the test card, above, below, to the right or to the left, it was possible to see the gap in the **C** or the **E** better. It is well known that the light sense of the retina away from the macula is better than that at the macula. In a sense this is a criticism of all night-vision tests, for we can see better than the record of a direct-vision test will show.

Latterly I have used a still simpler distance test card[3]—one that I think needs a minimum of form sense, and therefore one that relies almost wholly on the light sense, though still at the macula. The 5-metre distance test card is a board a foot square. This is covered with black velvet. The test objects are white disks half an inch in diameter, from four to seven in number, fixed on the velvet, each an eighth of an inch separate from the others.

On the board are four separate groups of white disks, each of different numbers, but arranged so as to suggest a common pattern. The groups are covered by another velvet-covered disk in which is a 3-inch hole. This cover is pivoted so that it can be turned to expose any of the four groups of white disks. The baseboard has a hanger at each corner, so that it can be hung four ways. This gives sixteen variations of the test. Before testing, the patient should be in the dark for fifteen minutes or, more conveniently, have a black velvet band clipped round the head so as to cover the eyes. Distance glasses, if needed, must be worn during the test.

The candle-box is fitted at 5 metres from the test card, so that the test is lighted by 1/269 foot-candle. The light that reaches the patient's eye is much less: ignoring loss by reflection, 1 m. from the test = 1/393; 2 m. = 1/527; 3 m. = 1/688; 4 m. = 1/871; 5 m. = 1/1075; 6 m. = 1/1302 of a foot-candle. The room is dark except for the candle rays. The patient stands beside the candle-box and looks towards the test card. A group of white disks is exposed. Most can see the massed white blur, and many can count the number of disks at 5 metres. A few can count at even 6.5 metres. If the patient cannot count at 5 metres he steps forward a foot at a time until he can count the disks. By recording the position of patients in half-metres thirteen grades, from 6.5 metres to 0.5 metre, are obtained. The average of four trials is enough usually. The value of this test is shown by the maximum distance at which one can both see and count the separate white spots. I find a fair average for normal-sighted persons is 5 metres. Those with 4-metres range should be safe at night. Those with 3-metres range or less had better stay indoors. Night-flying men should have a range of at least 6 metres.

It was of interest to check the relation of these indoor tests with outdoor conditions. One night after half an hour in the dark with these tests we stepped into the open air. The night for a moment seemed brilliant by contrast. Yet it was a dark night. There was a slight high mist; a few stars were to be seen, but no moon. There was so little light that with the **E** test the vision of normal persons (with 6/5 full-light vision) ranged only from 1/50 to 3/50. Yet it was easy to walk about, though the ground was on different levels and there were steps.

Experience shows that variations in night vision do not depend wholly upon a light sense. Apart from this there are many conditions that diminish night vision or vary it. Chief among these are: (1) the size of the pupils; (2) the

[1] "Test for Night Vision," designed by W. D. Wright, D.Sc., A.R.C.S., made by the Pitman Press, Bath. London: Sir Isaac Pitman and Sons. (25s.)
[2] *Lancet*, 1934, 2, 821.
[3] Disk Spotting Night-vision Test, made by Theodore Hamblin, Ltd., 15, Wigmore Street, London, W.1.

condition of the crystalline lens; and (3) the retinal integrity. Young folk, with their larger pupils, get more light into their eyes than older folk. This was well demonstrated by a doctor colleague: he had vision of 6/5 in each eye; the left pupil was larger than the right, and the left eye did better with all the night tests. Another colleague showed poor night vision; this was due to lens opacities, even though in normal light the vision was 6/9. Retinal disease has a serious effect upon the light sense; even excessive smoking affects the retina and reduces the night vision.

A paper on testing fitness for night vision[4] and another on night blindness[5] give detailed consideration of variations of sight, and include full biographies. The Report on Wartime Street Lighting (see p. 635) should be considered in this connexion.

There is no doubt that tests for night vision are of use. Dr. Wright has done good service by his designing. But some standard test that could be set up by an ophthalmic surgeon for himself, and yet would be the same for all, would serve still better.

AIR-RAID SHELTER POLICY

VIEWS OF A DOCTOR AND AN ARCHITECT

A Chadwick Lecture on air-raid shelters was delivered on April 8 jointly by Dr. S. L. Wright, who discussed hygienic considerations, and Mr. Philip O. Reece, an architect, who dealt with design and construction. Dr. WRIGHT said that large shelters raised problems of hygiene most difficult of solution, chief of which was the spread of communicable disease, whether air-borne (which was the most important) or by direct contact, inanimate objects, or insect vectors. In hospitals for infectious diseases the only effective method of countering droplet infection was to nurse the patients in separate cubicles. It was out of the question in shelters to provide cubicles for each person, but he suggested that a cubicle should be provided for each family unit, with the ventilation so arranged that the air from one cubicle could not enter another. The edges of the bunks should be at least 3 ft. apart, and the air turnover the maximum possible. The walls and floors should be smooth-finished so that they could be mopped down and dusted, the furnishing and bedding should be retained by the family and used only by them, and the cubicle be disinfected for new occupants.

A method of sterilization of air had not yet been discovered which, while completely innocuous, would bring the enclosed atmosphere up to the standard of fresh air. Air should approximate in standard of purity to the standard now expected in water supply, instead of being something equivalent to a sterilized sewage effluent. Spraying would be sufficient in corridors, sanitary annexes, and canteens. There was a danger of infection in the use of common sanitary conveniences, which could be met by proper supervision, an adequate supply of wash-basins, and elimination of the common roller towel. The necessity for washing the hands after visiting the lavatory and before eating must be emphasized. The habit of undressing at night, which would be possible in family cubicles, should be encouraged as a means of dealing with the problem of infestation.

One reason why not all people brought into contact with infection developed disease was the state of the general bodily health, closely related to the mental attitude, so that without undue exaggeration it might be said that in resistance to infection the dirty but cheerful were as safe as the clean but miserable. To encourage cheerfulness the shelters should be lighted to a reasonable standard—not less than 3 foot-candles in corridors, 4 to 5 in cubicles, 4 to 6 in sanitary annexes, and 7 to 9 in the canteen or communal dining room. Cubicles gave unlimited facilities for sick bays, medical officer's surgery, and first-aid points. Those in charge of aid posts would be the first to admit that without the sanitary provisions he had described their work was little more than a placebo. Although the last winter had been got through without epidemics, the same immunity might not persist. Pestilence followed in the wake of war and famine, and when it started could not be confined within national boundaries, so that all the weapons of environmental hygiene would be required.

Mr. P. O. REECE, from the architectural point of view, developed Dr. Wright's theme further. He said that in eighteen months of war shelter ideas had run the whole gamut from the Anderson with its maximum protection and minimum comfort to the indoor Morrison with its minimum protection and maximum comfort. There was no universal form of shelter equally suited to all conditions. Even the most enthusiastic supporter of deep shelters would have to review his proposals on account of the time and labour required. Instead of designing shelters having in view the effect of bombs of certain weight falling at certain distances, consideration should be given to the disintegrating effect of earth tremors caused by bomb explosions, and it might be wise to follow the methods employed in designing earthquake-resisting structures, whereby a shelter free to slide on the surface would be inherently safer than one embedded in the earth. This ideal shelter would be multicellular in form, made of reinforced concrete, each block holding, say, sixteen cubicles and each cubicle accommodating six persons—a family unit—with the sanitary annexe at one end. Bunks would be supported between cleats embedded in the concrete, with a table between the tiers, and lighting would be so provided in the walls as to give light in each bunk, not to throw a deep shadow, as at present, into the bottom bunk. These blocks, with their sixteen cubicles for ninety-six persons, should be arranged in a radial fashion around a central eating room, which would afford the maximum centralization of services, with consequent economy in drainage, electricity, and water supply. Independent mechanical ventilation would be supplied to each block, and such a system lent itself to easy gas-proofing. In one block provision should be made for surgery and sick bay. The number of houses destroyed by enemy action would probably steadily increase, and the rehousing of homeless people was likely to become one of the major problems of domestic policy; again, the possible outbreak of epidemics would necessitate the isolation of large numbers of people; and, thirdly, imminent threat of invasion would entail movements of troops to areas where extensive accommodation was not available. All these requirements, as well as mere protection against air attack, might be met by this type of shelter. Once constructed, the shelters could be set apart for any of these uses as circumstances might require, and even as they could be adapted during the war for a number of uses, they could be designed for the fulfilment of useful purposes after the war. Smaller shelters with four or eight cubicles could be constructed on the sites of demolished houses and converted into new houses when the war was over, while larger shelters would lend themselves to conversion as sports pavilions, club rooms, and for use for the increased social services that would be demanded when peace came. It was estimated that these shelters could be built for approximately £9 10s. per head—the estimated cost of the present mostly unsatisfactory shelters. Only cement, steel, and shuttering need be considered in their construction.

[5] Tansley, Katharine (1939). *J. Ophthal.*, **23**, 161.

A. B. Baker (*Amer. J. Path.*, 1941, **17**, 39) concludes that in cases of long-standing hypertension there is very little structural alteration in the average small cerebral artery, while the larger arteries often show arteriosclerotic changes with marked narrowing of the lumen. He believes that the narrowing of the larger vessels reduces the wear and tear on the smaller ones. In so-called "malignant hypertension," however, there are extensive changes in the small arteries, the elastica interna becoming reduplicated and the media undergoing rapid fibrosis and patchy hyalinization.

VEGETABLES AS FOOD

CONFERENCE OF NUTRITION EXPERTS

The third of a series of discussion-meetings organized by the Nutrition Panel of the Food Group of the Society of Chemical Industry was held at the British Medical Association House, London, just before Easter, with Sir E. J. RUSSELL, F.R.S., director of the Rothamsted Experimental Station, in the chair. Previous discussions had been on the merits of cheese and of the potato; this time it was on vegetables.

Chemical Composition of Vegetables

Dr. M. A. PYKE described the chemical composition of vegetable foods. The fat present in green vegetables, he said, was too small to affect the calorific value. In carbohydrate content, cabbages, cauliflowers, broccoli, spinach, and lettuce all contained less than 2%, roots from 2 to 10%, and legumes headed the list with 10 to 18%. With the exception of beetroot, spring onions, and parsnips, all vegetables might be classed as protein foods, but the low percentages were against their use as a major source of protein. As for minerals, green vegetables were the carriers of quite useful amounts of calcium, the richest vegetable in this respect being spinach. Mineral content varied in different varieties of the same vegetable and even in different parts of the plant. Thus the outer leaves of cabbage were richer in calcium than the inner. In respect of vitamins, β-carotene was present in green leaves in relatively large quantities. Green vegetables did not provide large amounts of vitamin B_1; dried pulses were a richer source of this vitamin. There was practically no vitamin D in vegetable foods, but they were an important source of vitamin C. Broccoli headed the list in this respect, and brussels sprouts were extremely good. The high vitamin value of mustard and cress was worth mentioning, especially as this plant could be grown by town dwellers. Asparagus and celery were of low nutritional value. Mushrooms formed a class by themselves, containing small amounts of the principal vitamins. Vegetables were primarily protective foods, and the principles to bear in mind in production and treatment were to choose crops which would yield the maximum amount of vitamin content per acre, and to destroy as little vitamin as possible in storage, preparation, and cooking.

Planning Vegetable Production

Dr. H. V. TAYLOR said that a rough estimate of vegetable production in this country was 3,000,000 tons, which, divided among the population of above 5 years of age, would give 45 oz. a head a week. The Scientific Food Policy Committee set up at the beginning of the war suggested that in order to maintain health the average consumption should be 6 oz. of vegetables a day; it appeared that there was a quantity available slightly in excess of this recommendation. But it must always be borne in mind that vegetables were foods, which meant that people must like them, otherwise there was no point in growing them. A deputation of growers had complained that the planting of brussels sprouts was wasteful, comparing the acreage yield with that of cabbage; but brussels sprouts were appreciated by the public, whereas cabbage was only tolerated, and sprouts were more nutritious, and did not disappear, as cabbage did, with a bad winter. When the war broke out a survey was made of crops regarded as useless from a nutritional point of view; but, with scarcity of meat supplies, some of these plants had to be restored for their flavouring value. Onions were the lowest of vegetables from the nutritional point of view, but 15,000 acres had to be apportioned to them, and altogether 80,000 acres had to be devoted to crops which the nutrition expert would condemn, simply on account of their flavouring value for the drab wartime meal. Nobody had attached much importance to pickles, but pickles were surprisingly popular among Service men. The materials for making pickles in the past had been imported from over-seas, but now a big acreage of land had to be set aside for this purpose. Of the nutritional value of the carrot experts were convinced, and there was a record crop last year of 380,000 tons as against a normal 140,000. But at first carrots were not very popular, and special measures had to be taken by the Ministry of Food to recommend the carrot, with the result that during the last three months the consumption had been 50,000 tons a month, or double the rate of peacetime. As for peas and beans, unless the production of this group was very much expanded the consumption must be much lower than normal. It had been arranged to increase the production of dried peas by 45,000 acres. In normal times one-third of the supply of tomatoes was raised in this country, one-third came from the Channel Islands, and one-third from the Canaries. In view of the loss of the Channel Islands and the difficulties of shipping, steps had been taken to convert greenhouses devoted to flowers to the production of the tomato; an additional 15,000 tons was being raised this year, to be followed by another 15,000 tons next year. The consumption of cauliflower and broccoli was 430,000 tons, an average of 8 oz. a head a week. The conclusions he drew as a planner of vegetable production were that it was impossible to settle the planning on the basis of one or other character of the vegetable; to select only those which the nutritional expert said were the best and to ignore popular preferences would be quite wrong.

Effect of Cooking on Vitamins

Miss M. OLLIVER, in dealing with the effect of cooking on the nutritive value of vegetables, said that the housewife should have the vegetables fresh, if possible from her own garden. Waste must be avoided; to throw away the outer leaves was to destroy valuable material. Roots should be cut very thin or scraped. Green vegetables should be boiled fairly rapidly, using the minimum quantity of water, and the material should not be kept hot. Roots could be boiled, baked, steamed, or fried; salt should be added as it made the vegetable more palatable, and soda used with caution. As to the effect of cooking upon vitamins, carotene was relatively stable and also insoluble in water, and fairly good retention might be expected. The main loss of B_1 seemed to be due to the extraction into the cooking water, B_1 being easily soluble. In most diets, except for cooked vegetables, people did not get vitamin C at all. In times of peace vitamin C was supplied by canned foods and oranges, which were now scarce. It had been said that vitamin C was easily destroyed, but in her experimental work she had found that destruction by boiling was very small. Extraction, however, was great, and only about one-third was retained. There was greater retention with green peas and brussels sprouts than with cabbage or kale. It was possible to get one's normal requirements of vitamin C in one helping of greens if they were cooked under proper conditions, but housewives should be encouraged, if they boiled green vegetables, to retain the cooking water and use it for soups. The retention of ascorbic acid was much higher when the vegetables were steamed, though there were disadvantages in that method on the score of palatability. There was rapid destruction of ascorbic acid with continued cooking or keeping hot. Within forty minutes only about 60% was retained, and after about an hour and a half only a very small proportion.

Effect of Canning

The final paper, by Mr. W. B. ADAM, was on the effect of canning on nutritive value. Loss of nutrient value in canned foods, he said, might occur at any stage of the journey from the field through the cannery to the table, especially during the operation known as blanching, which resulted in some loss of vitamins B_1 and C. There was slight destruction of vitamin C during storage. Canned food diet gave results which were similar in all respects to those obtained from shop-purchased home-cooked food. The vitamin B_1 content might be slightly less than in home-cooked vegetables, but in vitamin C the canned vegetable might be superior.

The CHAIRMAN pointed out that in the change of diet in wartime practicability was the governing consideration. Vegetables could not form an entire diet—they did not, for example, supply any important fat constituents—but fresh vegetables supplied a protein of value at a time when there was a shortage of first-class proteins in cheese and meat. The protein of the green leaf was associated with a good deal of cellulose, which could not be very easily digested, but there was a case for studying and separating this protein from the rest of the constituents of the green leaf. Fruits did not compare with vegetables for nutrients, which was reasonable at a time when a good many gardens and nurseries were used

turned over from fruit to vegetables. In the change-over of diet whereby enlarged amounts of some foods became available and diminished amounts of others, the treatment of food by cooking or canning became of greater importance.

The earlier discussions were reported in the *Journal*, on the potato, November 23, 1940, p. 717, and on the composition of cheese, December 14, 1940, p. 838.

CANCER RESEARCH

WORK IN PROGRESS

In the past an important feature of annual reports of the Imperial Cancer Research Fund has been the Director's critical remarks on matters of current interest in cancer research. This feature, as many will regret, is absent from the most recent report,[1] that for 1940–1, the scientific section being now more strictly limited to the work of the Fund's own laboratories. Nevertheless, it is still possible to glean much concerning the present outlook of the staff of this the oldest of all institutes dedicated solely to the study of cancer. Much of the work is of general interest.

Brief mention is made of a paper by Dr. L. Foulds ("The Histological Analysis of Tumours: a Critical Review," *Amer. J. Cancer*, 1940, **39**, 1), which many have regarded as of considerable importance. The paper deals in a very thoughtful way with influences which determine what structural characters shall be exhibited by different tumours. It relates the relevant facts and discusses the relative parts played by tumour cells and by host tissues. In the past, histological studies have constituted a very prominent part of the activities of the Fund, and it is evident that such studies are still thought, and found, capable of yielding fundamental knowledge of cancer.

Carcinogenic Hydrocarbons

It will be remembered that Dr. B. D. Pullinger began a study of the very earliest changes which are induced in mouse skin by carcinogenic hydrocarbons and that she described cellular characteristics which, appearing as early as the third or fourth day, seemed to be a specific response to the presence of these carcinogens. She has now extended her investigations. Two more carcinogenic hydrocarbons have been examined and the cellular effects of both have proved essentially similar to those of the carcinogens previously tested, whilst in a further series of control non-carcinogenic substances not one has produced other than quite non-specific changes. A singular fact shown by the more recent experiments is that the potency of carcinogenic hydrocarbons as judged by early effects on mouse epidermal cells does not always run parallel with relative tumour-producing potency. The significance of the characteristic early changes is not discussed, and one is left with the impression that Dr. Pullinger is not as yet prepared to claim that they are themselves of cancerous nature.

Mr. H. G. Crabtree has continued his effort to find how far the application of compounds which alter the metabolism of the cell by inhibiting glycolysis can influence the induction of skin cancers in mice by carcinogenic hydrocarbons. One experiment may be mentioned. In it a preliminary period of painting with benzpyrene was followed by a period during which chloracetone was applied. At the twenty-ninth week there were, in the thirty mice treated in this way, eighteen growing tumours, of which eight were epitheliomas; whereas in the control group treated with benzpyrene alone three small papillomas were all that could be found. This result recalls a phenomenon recently described by Rous and Kidd, who tarred the ears of rabbits and found that cells of papillomata which had regressed and disappeared after tarring had been discontinued might again become active, even to the exhibition of fully malignant characters, under the influence of conditions usually regarded as non-carcinogenic—painting with turpentine, for instance.

The problem facing Dr. R. J. Ludford has been to find why carcinogenic hydrocarbons which produce cancers in the living body seem not to induce malignant change in cells grown in tissue culture, although, as he himself has shown, filtrates of fowl sarcomas will readily induce malignant change in tissue cultures of fowl fibroblasts. Under the impression that technical procedures may possibly have been at fault many improvements have been effected. For instance, Dr. Ludford has now used cells taken from closely inbred strains of mice, because when such cells are inoculated into other mice of the same pure strain antagonistic reactions are minimal or entirely absent. Cell cultures have been treated with 3:4-benzpyrene or with methylcholanthrene over periods varying from a few days to six months, but all with entirely negative results; inoculation into mice has failed to produce tumours. Cytological studies of the treated tissue cultures have been made and many derangements of cell division have been observed, but nothing really suggestive of malignant change has been seen. The problem remains and the work continues.

Virus Tumours of Fowls

Study of virus tumours of fowls has not been shelved. Dr. W. J. Purdy, who is seconded from the National Institute for Medical Research, has studied Fujinami tumours growing in ducks and has reached conclusions similar to those recently announced by Dr. Kidd of the Rockefeller Institute, who studied the Shope papilloma growing in domestic rabbits. Both workers find that when several separate tumours are growing in an animal all tend to retrogress simultaneously if they retrogress at all. It is thought that such simultaneous retrogressions can be co-ordinated only by something circulating in the body fluids. At the time the Fujinami tumour retrogresses (a phenomenon characteristic of this tumour when growing in ducks) the blood serum of the host commonly fails to neutralize active filtrate of Fujinami tumour. Thus there seems to be no circulating anti-viral factor. This leaves the possibility of an anti-cell factor responsible for the co-ordinated retrogressions. Dr. Purdy and Dr. Ludford, working in co-operation, have used tissue-culture methods to investigate this suggestion. Cells of the Fujinami tumour were grown in plasma obtained from a duck in which a Fujinami tumour had grown well and then had just started to retrogress—a time at which the hypothetical anti-cell antibody might be expected to have attained its greatest potency—but the tumour cells grew just as well and liquefied the plasma just as readily as in control cultures. And so we are left with the probability that some elusive anti-tumour-cell influence may be present in the host and yet cannot be found by a method which would appear to be adequate.

Oestrogens and Pituitary Changes

It is known that when an oestrogen is used to produce mammary tumours in mice the general hormonal imbalance which results is accompanied by changes in the pituitary gland. Dr. E. Vazquez-Lopez is at present engaged in a detailed histological study of such changes. He has found that in these mice the pituitary changes are more widespread than has usually been supposed, appear throughout the organ, and are mainly of a character suggestive of hyperactivity. Changes originating in the pars intermedia may be specially mentioned. In the cells of this region the Golgi apparatus is greatly hypertrophied, a fact which is taken as an indication of increased secretory activity; there is increased migration of these cells to the pars nervosa, where their disintegration results in a correspondingly great increase in the number of Herring bodies; and the migration of these bodies to the tuber cinereum and the third ventricle can be traced with unusual ease. These Herring bodies, of course, are those granules which have been regarded as being, or bearing, the hormonal secretion of the posterior lobe of the pituitary.

It is known that both the activity of the anterior lobe of the pituitary gland and the character of the secretion can be changed by nerve impulses which pass by way of the central nervous system, but details of the nervous connexions are for the most part unknown. Dr. Vazquez-Lopez has now found in the horse certain bundles of nerve fibres which pass from the tuber cinereum to the pars tuberalis and thence, probably, to the anterior lobe. The nerve tract passing between the pars nervosa and the base of the brain is known, but Dr. Vazquez-Lopez has now shown that in the

[1] Thirty-eighth Annual Report, 1940–1. Published from the Office, Royal College of Surgeons, Lincoln's Inn Fields, W.C.2.

pars nervosa there are far more nerve fibres than has been supposed and that some of these pass into the pars intermedia. In both these regions he has demonstrated multitudes of nerve endings. These suggest a functional activity not fully appreciated hitherto.

Hortega cells have hitherto been thought to occur in all parts of the central nervous system with the exception only of the pars nervosa of the pituitary. Dr. Vazquez-Lopez, studying conditions in the horse, has now observed that in this animal Hortega cells do occur and, indeed, may be seen to constitute an important part of the architecture of the gland.

Co-operation in Research

In this 1940-1 report of the Imperial Cancer Research Fund it is pleasing to note once again the generous co-operation which exists between the various institutions devoted to medical research. Acknowledgments are found, for instance, that for gifts of chemicals Dr. Pullinger is indebted to Profs. Kennaway and Cook of the Royal Cancer Hospital; that Dr. Vazquez-Lopez is indebted to Mr. Glover and the Medical Research Council for provision of pituitary glands of horse, ox, and sheep; and that Mrs. Holmes is indebted to Sir Cuthbert Wallace and Mount Vernon Hospital for helpful collaboration in studies of the cause of the vomiting which sometimes follows exposure to *x* rays. Dr. Ludford of the Imperial Cancer Research Fund has co-operated with Dr. Emmens of the staff of the National Institute for Medical Research in experiments demanding expert knowledge both of tissue-culture methods and of endocrinology. The Fund has maintained its tumour strains and placed these at the disposal of workers in different parts of the country.

PHARMACEUTICAL SOCIETY CENTENARY

COMMEMORATIONS IN LONDON

The Pharmaceutical Society of Great Britain commemorated its centenary on April 15 by a meeting at Conway Hall, which was addressed by Sir John Anderson, Lord President of the Council. It was preceded by a thanksgiving service at St. Pancras Parish Church, at which the vicar of St. Pancras, the Right Rev. Bishop Crotty, was the preacher. In his sermon he said that the story of the Society was part of the much larger story of the development of modern medical science and practice from quite empirical beginnings. The history of medicine revealed an increasing differentiation of functions, originally quite confused and unrelated, into the stabilized and orderly activities of physician, surgeon, and apothecary. The Pharmaceutical Society was a section of the great team in the field of healing. By the standards it had upheld it had rendered a service not only to its members but to the community. It goes without saying that the lesson read at the service was the well-known passage from the 38th chapter of Ecclesiasticus.

The assembly later in the day was presided over by Mr. Walter Deacon, the president of the Society, who, in a brief address, recalled the names of the founders—William Allen, the Quaker chemist, and Jacob Bell, whose efforts were supported by an army of unrecorded workers. They had sought to emphasize the importance of education, examination, qualification, professional unity, and discipline in a world all too much concerned with purely business problems.

The secretary, Mr. H. N. Linstead, read a number of greetings which had been received from professional and scientific organizations in all parts of the world. These included the Royal College of Physicians, the University of London, the British Medical Association, the Linnean Society, the Institute of Chemistry, and the Chemical Society. The message sent by the British Medical Association, signed by the President, Dr. Thomas Fraser, read:

"Our two professions have been closely associated from time immemorial in the service of the public, and we entertain the hope that this friendly and fruitful co-operation will continue. It is gratifying to me to recall that the British Medical Association from an early period in your Socie history has collaborated with it in work for the advancem of medicine and of pharmacy, which has enabled both p fessions to bring benefits to the community."

Sir John Anderson's Address

Sir John Anderson said that his own connexion with Society began in the early days of the National Health Ins ance Act, when he remembered interesting discussions on st topics as stock mixtures and the pricing of prescriptions. the beginning of the last war he was responsible for ensuri a continuous supply of all necessary drugs and medicines, a there followed a period of close and fruitful co-operati between chemists and pharmacists on the one hand and D partments of State on the other, with the result that, in sp of an unfortunate dependence on Germany before the w for much of the supplies of drugs and medicines, it w possible to get through without any serious or even noticeat shortage. The work embodied in the Therapeutic Substanc Act sprang directly from what was done at that time. At t Home Office he had had further contacts with the Society ov the Dangerous Drugs Act and the Pharmacy and Poisons A Therefore it was not strange that with this experience of thir years a member of His Majesty's Government should come congratulate the Society on its achievements and wish it w for the future. It was a matter of historical fact (Sir Jol Anderson continued) that the establishment of the Pharm ceutical Society arose directly out of an attempt on the pa of the medical profession to secure for itself greater priv leges at the expense of the druggists. The pharmaceutical ar the medical professions had some remarkable differences. I the medical profession there were many organizations concerne with the advancement of the interests of the profession, wit the licensing of practitioners, or with medical learning, and th General Medical Council, the custodian of educational an ethical standards. The pharmacists, on the other hand, ha contrived to combine all these functions in a single organiza tion. How easily they might at any time during the last hun dred years have slipped back into the position of a body o privileged shopkeepers concerned only with the furtherance of their material interests!

As a profession they had certain legal privileges. Some perhaps thought that those privileges were inadequate and not in fair correspondence with their obligations; but Parliament did not readily confer exclusive rights upon any section of the community; indeed he believed it never did so unless one simple test was satisfied—namely, that the privilege which was sought was necessary in the public interest. Turning to some of the achievements of the Society, the Lord President said that for fifty years—a period of spectacular, almost revolutionary, progress in medical treatment—the Society had maintained chemical laboratories under the charge of highly competent chemists. Many of the remedies now used in medicine were the products of the chemical laboratory in contrast with the natural vegetable and mineral products whose composition had formed the chief part of the pharmacist's training. The foundation of the new science of chemotherapy had called for intimate collaboration between the chemist, the pharmacologist, and the clinician. The development of all kinds of biological products had completely changed the work of the pharmacists. Again, in the Society's pharmaceutical laboratories, opened by the late Mr. Neville Chamberlain when he was Minister of Health, work of the greatest national importance was being done, particularly in the standardization of therapeutic substances and in the field of nutrition. These laboratories were the only institution in the country where manufacturers could have the vitamin content of foodstuffs and drugs determined. Among the problems of the reconstructive period after the war none would make a stronger claim than those connected with nutrition. He touched, finally, on the many-sided war work of the Society, and ended by congratulating it on its steadfast adherence to the high principles of its founders and its substantial contributions to the common good.

"Jacob Bell and Some Others"

A vote of thanks to Sir John Anderson was carried on the motion of Mr. F. G. Wells, vice-president, seconded by Dr. A. R. Melhuish, chairman of the British Pharmaceutical Conference. The final event was a three-act play written by

Hugh Linstead, the Society's secretary, entitled "Jacob Bell and Some Others." It related how young Bell formed the Society against great opposition, and went for help to William Allen, who became the first president. The third act was staged at the *Crown and Anchor Tavern in the Strand* on April 15, 1841, when the following resolution was carried:

"That for the purpose of protecting the permanent interests and increasing the respectability of chemists and druggists an Association now be formed under the title 'The Pharmaceutical Society of Great Britain.'"

The audience of 1941 played its part, and when the chairman of that meeting a century ago put the motion it was greeted with loud shouts of "Aye" from the spiritual descendants of those pioneers. The twelve actors carried through their parts extraordinarily well, and the play had its amusing passages.

AWARDS FOR GALLANTRY IN CIVIL DEFENCE

The award of the George Medal to Dr. H. R. B. Norman, resident assistant physician, St. Thomas's Hospital, London, to Mr. P. B. Maling, medical student, and to Mr. H. E. Frewer, assistant clerk of works, is announced in a *Supplement* to the *London Gazette* dated April 11.

Dr. HARRY RUMBOLD BATHURST NORMAN, Mr. PETER BROMLEY MALING, and Mr. HERBERT EDWIN FREWER: "After St. Thomas's Hospital had been hit by a high-explosive bomb it was found that two of the staff were trapped in the wreckage. Mr. Frewer formed a rescue party and was joined by Dr. Norman and Mr. Maling. The debris under which the men were buried had crashed through the ground floor into the basement. The dispensary stores had been destroyed in the explosion and the stocks of alcohol and acids caught fire. Gas was escaping from broken mains and masonry was continually falling. Mr. Frewer led the rescue party into this very dangerous area. Dr. Norman, assisted by Mr. Maling, burrowed into the debris and was able to give morphine injections to the injured men. They then continued the rescue work and ultimately succeeded in extricating the casualties, who undoubtedly owed their lives to the gallant conduct of the rescuers."

Local News

SCOTLAND

Health of Wartime Glasgow

The latest report of the medical officer of health for the city of Glasgow (Dr. A. S. M. Macgregor) covers the year 1939, but introduces some matters relating to 1940. The lower death rates and reduction in the incidence of common diseases in 1939 recall the experiences of London and other cities in the year which saw the outbreak of war, but in 1940 Glasgow showed some disquieting features. The general death rate in 1939—13.3 per 1,000—was the lowest on record. There were fewer deaths due to respiratory and infectious diseases. Acute pneumonia, the most common and serious of the diseases of respiration, caused 867 deaths as compared with 1,158 in 1938 and 1,543 in 1937. There were low death rates from measles, scarlet fever, and dysentery, though the rates for whooping-cough and diphtheria were higher than those for the preceding year. Infant mortality fell to 80 per 1,000 births, the usual range being between 90 and 100. Deaths due to puerperal infection numbered thirty as compared with fifty the year before. During the first quarter of 1940, however, there was an outbreak of influenza concurrently with a long spell of severe weather, and these factors gave rise to a relatively severe incidence of pneumonia. By the end of January the death rate had risen to 41.1 per 1,000 of the population and did not fall to normal levels until the end of March. There was also a large outbreak of paratyphoid fever with 274 cases in the city, but only three deaths. For the first time for many years measles was prevalent in summer instead of in winter. The outbreak expected in November, 1939, did not arrive until April, 1940, continued throughout the summer, and tapered off in August. In the later part of 1940 diphtheria in Glasgow, in common with some other parts of the country, reached its highest known prevalence. The medical officer of health considers that these experiences cannot be related directly to the conditions arising out of the war; apart from the influenza outbreak and this prevalence of diphtheria the health of the city was almost as favourable as it was in 1939. The Emergency Hospital Scheme of the Department of Health has not led to any neglect of ordinary civilian needs. Although a large number of empty hospital beds have had to be maintained, the number of patients admitted to the general hospitals of the corporation in 1939 was only 5% below what it was in 1938.

Edinburgh Gift to Polish Students

On April 18 in Sir John Fraser's operating theatre at the Edinburgh Royal Infirmary, Mr. James Watt, LL.D., president of the Graduates' Association of the University, handed to the Polish Medical Faculty, for the use of its students, a set of the textbooks which are in common use in the medical curriculum of Edinburgh University. Among those who attended the ceremony were Prof. Jurasz, Dean of the Polish Medical Faculty; Principal Sir Thomas Holland, Vice-Chancellor of the University; Mr. W. J. Struthers, secretary of the Royal College of Surgeons; Prof. J. R. Learmonth, of the Edinburgh Chair of Surgery; Colonel Stewart, Superintendent of the Royal Infirmary; and members of the Polish Faculty. Dr. Watt, in making the presentation on behalf of his Association, expressed regret that Sir John Fraser himself could not attend as he was detained on business in the South. Prof. Jurasz gratefully accepted the books on behalf of his students; he expressed warm appreciation of the generosity shown to his fellow-countrymen since they came to Scotland, and particularly thanked the institutions and associations linked with Edinburgh University. Sir Thomas Holland said that the giving of this nucleus for the Polish Medical Faculty's library was an expression of the feelings of 20,000 graduates of Edinburgh spread over the world. The forming of the Polish Medical Faculty in Edinburgh was a milestone in the history of medicine.

ENGLAND AND WALES

Co-ordination of Hospital Services

At the annual general meeting of the British Hospitals Association Sir Bernard Docker, who has lately been elected chairman of council of that body in succession to Sir Harold Pink, spoke on hospital regionalization. The Sankey Commission, he said, limited its findings to the regionalization of voluntary hospitals, but Lord Sankey had since given his public approval to a more comprehensive plan which would embrace public authority as well as voluntary hospitals. Indeed, the Provisional Central Council set up by the association itself to carry into effect the Commission's report had soon realized that full co-ordination of hospital services was not possible unless the co-operation of the public health services was also assured. Another powerful factor was the creation of Lord Nuffield's Provincial Hospitals Trust, one of the objects of which was to encourage the organization of regional councils representative of both types of hospitals. Representatives of the British Hospitals Association had been appointed to the council of the Trust, and the liaison would become still closer with the adoption of some recent proposals. Sir Bernard Docker pleaded for active regional committees in the association, which would join effectively with the regional councils of the Nuffield Trust and enable the association as representing the voluntary hospitals to play its part in this field of post-war reconstruction. There were some, he said, who thought it inadvisable to proceed with regionalization at all during the war, but he could not share that view. On the contrary, no time should be lost in building up a consolidated service; that was the view also of the Nuffield Trust. Plans were being prepared in all directions to meet the conditions which would arise after the war, and it was most

undesirable that in the field of hospital service such action should be deferred. The duty of the British Hospitals Association was to ensure that the special position of voluntary hospitals was recognized and to take its part in framing any scheme for the co-ordination of the hospital services of the country. With that in view, the close co-operation of the association with King Edward's Hospital Fund for London, the Nuffield Trust, and other interested organizations was necessary for the formulation of an agreed policy. It was announced at the meeting amid general regret that Mr. R. H. P. Orde had retired from the position of honorary secretary of the association on account of ill-health, and tribute was paid by the chairman to his services in various capacities to the voluntary hospitals extending over a period of forty-two years. Mr. J. P. Wetenhall, house-governor of the West End Hospital for Nervous Diseases, had been appointed to succeed Mr. Orde.

Some Food Facts

The *Wartime Nutrition Bulletin*,[1] which in March reached its seventh issue, contains an interesting summary of the bread position. A brown loaf of 85% extraction from the grain is to be marketed, and probably also the "fortified" loaf, which contains the synthetic vitamin B_1 but none of the other members of the vitamin B group which exist in wholemeal bread. The normal pre-war sale of brown bread is, however, reputed to be not more than 10% of the total. The *Bulletin* also gives a full analysis of the milk situation, particularly the shortages which occurred at the end of last year in Brighton, Manchester and other Lancashire towns, Lincoln, and South Wales. One cause for this is said to have been the official delay in fixing prices and in making known the plans for distribution of foodstuffs. This delay, which seems unfortunately to have occurred again this year, makes farmers tend to slaughter rather than to increase their stocks. The prevalence of mastitis also greatly diminishes the milk supply—to an extent of some 4 to 7% and a sum of £2½ million a year, though only £5,000 is being spent annually in research on methods of combating the disease. The shortage was partly overcome by diverting milk from milk-drying plants, so that the sale of liquid milk is said to have risen by 18%. This increase may not be shared equally throughout the community. The Oxford Institute of Statistics reports, on a small sample of working-class budgets, that between May and October, 1940, there was a decline of 11 or 12% in consumption. In the summer months there is, of course, a milk surplus, which is to be used in cheese manufacture, but this is unlikely to bring the cheese supplies to normal. This is unfortunate, since with rising prices many poor people may be consuming little animal protein. Prof. Bowley found that when the bacon ration was 8 oz. only a small minority of working-class families took their full quota.

Because of the necessity to conserve shipping space, much potential first-class food will now be wasted or diverted to commercial purposes. Palestine in 1939–40 sent us only 8 million boxes of citrus fruits as against 15 million the year before. Much of Jamaica's banana crop will be destroyed or processed for commercial use. In West Africa in 1940, 20,000 tons of cocoa were burnt, though Britain has undertaken to buy and market the whole Nigerian and Gold Coast crop for the duration. The Government has also arranged with the French Cameroons to purchase cocoa, bananas, and coffee, the bananas and coffee to be disposed of locally. In the British Cameroons the restriction on banana exports is likely to lead to diminished plantation areas; bananas may be dried and powdered and used locally for bread-making.

As against this somewhat pessimistic picture, communal feeding is increasing steadily and nutritious food is thus being provided cheaply; in some districts free meals are available for the poorest sections of the community, and at a cost of 3d., 4d., and 5d. for those who can afford to pay. The charges and arrangements vary considerably from district to district, so that it is difficult to give a composite picture—but the general trend, cheapness with nourishment, is in the right direction.

Reports of Societies

URINARY ANTISEPSIS

At a meeting of the Royal Academy of Medicine in Ireland on March 7, the chair was taken by the President, Dr. R. H. MICKS, and Dr. P. T. MCNALLY read a paper on the effects of sulphonamides in the urine.

He summarized *in vitro* experiments on the action of sulphanilamide, sulphapyridine, sulphathiazole, and sulphmethylthiazole on the growth of *Proteus vulgaris*, *Staph. pyogenes*, *Bact. coli*, and *Str. faecalis* in urine, and remarked that the results closely followed those of *in vivo* experiments. None of the drugs had any effect on the *Str. faecalis*, but mandelic acid was usually successful in dealing with this infection. On the other three organisms sulphapyridine had the most effective action. Sulphathiazole *in vitro* had proved disappointing against *Staph. pyogenes*.

Prof. T. W. DILLON asked at what concentration efficient bactericidal action was obtained. Sulphathiazole was absorbed, and excreted, much more rapidly than sulphapyridine. Dr. OLIVER FITZGERALD suggested that urine was not a dependable culture medium when determining the bactericidal action of sulphapyridine. Mr. J. C. FLOOD observed that urine might contain bacteria as a result of excretion from the blood stream or direct extension from an infection of the genito-urinary tract. He asked whether normal urine were itself bactericidal, and in what form the drugs were excreted. He thought it important to remember that the disease was not in the urine, any more than a respiratory disease was in the sputum. Dr. A. R. PARSONS was disappointed that no good results had been obtained for *Str. faecalis*. American journals had reported very good results with sulphapyridine. He thought that half the sulphanilamide dose was eliminated unchanged and the other half as the acetyl derivative.

The PRESIDENT hoped that Dr. McNally would collaborate with the clinicians; simple pyelitis was in everyone's mind. Most workers had found it not difficult to clear up the urine with the older drugs, but pyelitis had a definite tendency to clear up of itself. It was difficult to apply laboratory work to patients; for one reason they suffered from thirst if their fluids were too restricted. Satisfactory clinical results could often be obtained if the amount of fluid were increased without increasing the amount of the drug. He asked if the *p*H should be varied with the drug selected and whether there were significant resistance to these drugs.

Dr. MCNALLY, in reply, said that bactericidal action depended almost entirely on the initial inoculum used; he had tried varying the *p*H and had found that an alkaline urine produced better results with all the drugs. (An annotation on this subject appeared in the *Journal* of April 5, p. 521.)

Hyperventilation Syndrome

Dr. D. K. O'DONOVAN, in a paper on hyperventilation syndrome, outlined the symptoms and treatment, and divided the patients into a hypersensitive group, who developed symptoms after less than two minutes, and the larger group whose sensitivity was normal. He then described three "hypersensitive" cases. In one the sensitivity was affected by relatively minute changes in blood calcium and the patient was cured by large doses of calcium, phosphorus, and vitamin D by mouth. Another patient had low blood chloride due to vomiting. The syndrome was important in the clinical picture of parathyroid tetany, and hyperventilation tetany was closely related to the other tetanies. A low serum phosphate after the subsidence of symptoms was not diagnostic for the hypersensitive group.

Dr. E. HARVEY mentioned the importance of calcium for patients who suffered from fainting attacks, and asked if Dr. O'Donovan had considered the effect of the other ions. A patient might have a fairly normal calcium and suffer from tetany because of an overbalance of potassium and ammonium ions. Dr. P. T. O'FARRELL said that these cases might be labelled epilepsy or hysteria. Dr. W. R. F. COLLIS asked how acute tetany should be controlled in children and what was the exact mechanism of tetany in alkalosis. Dr. D. M. MITCHELL asked

whether anyone who had hyperventilation for long enough would go into tetany; he believed hysterics sometimes did. Prof. J. M. O'CONNOR said that in these patients the *p*H of the body had lost its normal steadiness. When the *p*H first rose the respiration decreased and the central nervous system became peaceful; why then did it become excited when the *p*H went still higher? The insulin convulsion followed the fall in metabolism produced by the insulin. Dr. ALAN THOMPSON mentioned that acapnia might result from the depth or the rapidity of the respirations, as in cerebral haemorrhage, pneumonia, and possibly in hypoglycaemic coma. Hyperventilation might occur if an iron lung were not properly adjusted—and also in fixed acidosis, but he had never observed the syndrome in these cases. Dr. OLIVER FITZGERALD referred to adrenaline as a producer of tetany and of the known relation between potassium and adrenaline; he asked if calcium had any similar relation.

Correspondence

Rehabilitation of the Injured

SIR,—Mr. E. A. Nicoll, in his most valuable article (April 5, p. 501), has again proved that the months and years of incapacity which so often follow industrial injury can be avoided by properly controlled rehabilitation. He has confirmed the experience of Dr. Moore at Crewe and of Mr. Griffiths at Greenwich. Within a few days of reading his article I visited the Rehabilitation Centre at Mansfield and found twenty or thirty miners working hard, developing muscles, mobilizing joints, overcoming inertia, and co-operating enthusiastically with their very capable physiotherapist, Mr. Colson, C.S.M.M.G. None were willing to admit of boredom; all were happy and cheerful; all were on their way to recovery. What a contrast with the miserable victims of industrial injury who tread their weary path from one consulting room to the next, who are reported upon at monthly intervals, and who, having lost the will to recover, steadily become enmeshed in the medico-legal web. As I have written elsewhere, "With the stimulating atmosphere of friendly rivalry, the enthusiasm of the crowd which contrasts so sharply with the helpless despair of the individual, and with carefully graduated physical stresses, more can be done by a few weeks of rehabilitation treatment than by months of 'light work' or years of massage."

The tragedy is that, knowing the solution to the problem, we are failing to apply it. In days of peace 200,000 fractures were sustained in this country each year. Allowing for injuries other than fractures, the figure should be doubled or even trebled, and with the increased risks of war we may well find that the figure exceeds half a million. Rehabilitation treatment is available for thirty men at Mansfield, for thirty at Crewe, and for thirty at Greenwich. What is happening to the other 499,000 odd? A great army of industrial workers is being wasted at a time when man-power is of such vital importance that women are being called upon to take their place in industry. Rehabilitation centres must be established forthwith at every place where fractures are treated.

It is to be noted that remedial workshops are not rehabilitation centres. Similarly, occupational therapy centres are not rehabilitation centres. Useful as these additional measures may be, the basis of rehabilitation depends upon direct contact between surgeon and patient. As Mr. Nicoll so rightly emphasizes, the individual must be inspired, his confidence must be gained, he must learn that recovery will come by his own unremitting efforts. Only after that are remedial workshops, occupational therapy centres, and group exercises by P.T. instructors of any value.—I am, etc.,

Liverpool, April 15. R. WATSON-JONES.

SIR,—In your leading article on rehabilitation of the injured (April 5, p. 519) mention was made of three rehabilitation centres, each for a particular trade: Berry Hill Hall for miners, the L.M.S. centre at Crewe for railway workers, and the Albert Dock Hospital for seamen. May I point out that the Albert Dock centre is not restricted to seamen. The majority of cases are in dock labourers or workers in the various factories in the dock area, and comprise members of a large variety of trades associated with heavy industry.

The running of a clinic of this nature emphasizes certain difficulties more than does a clinic such as Mr. E. A. Nicoll describes (p. 501) at Berry Hill Hall. When all the patients come from the same industrial organization and the clinic is part of that organization, it appears possible to exert control and discipline in employing set exercises, but in a clinic which caters for patients from any source, with a purely voluntary attendance, an attempt to make the men pull weights and perform strenuous physical exercises may lead to slackness and irregular attendance. Dr. Bohler relied almost entirely on remedial exercises, but his clinic was run with a military discipline that no English workman would tolerate. Undisguised exercises, moreover, sometimes have a bad psychological effect on the patient, emphasizing disability and pain, and causing despondency when recovery is slow. At a mixed clinic, therefore, especially where the majority of patients are not removed from their home surroundings to what approximates to a convalescent home, pure remedial exercises may be difficult to employ as the basis of treatment. By the greater use of recreational activity, selectivity suffers to a certain extent, but some graduation of effort can be achieved by a good trainer, and greater co-operation is obtained from the men. It is found that a large proportion of patients will recover with general measures, and the few that do not respond satisfactorily can be then tried separately on set exercises.

Occupational therapy, the third method of treatment mentioned by Mr. Nicoll, is probably the most difficult to attempt in a clinic recruited from all and sundry. For instance, at the Albert Dock clinic a garden was started, but the majority of men required a bribe of beer to work in it. They thought that their time would be better spent in their own home gardens. On one occasion, when the men were asked to help remove a heap of coal that had been dumped accidentally on the playing area; there was a complaint leading to a conflict with the local trade union leaders.

A fourth and most important part of treatment is psychology: in fact, it may be said that all forms of physical treatment will often fail if this is neglected. First, as Mr. Nicoll emphasizes, the workman must be convinced that getting well is hard work and a whole-time job. Secondly, every attempt should be made to relieve his mind of financial worries and despair of getting another job when he is discharged from hospital. Under the influence of these two factors, slight pain and physical impairment, insufficient in themselves to prevent a return to work, can cause total disability and make futile all efforts directed solely to bone alignment and muscle function. They contribute largely to the considerable time-gap (sometimes years) that exists between the duration of hospital treatment (regarded by many clinics in their statistics as the date of cure) and the time off work. No injured workman can be honestly regarded as recovered until he is actually doing work of a similar nature to his pre-accident employment. The ideal to aim at is never to discharge a workman except into a job that is waiting for him, and then to be prepared to take him back for further treatment if, after a week or so, he finds he is still unable to do the work. This is the only way that true statistics can be obtained. It would play havoc with many claims of successful end-results and quick recovery times, but it would greatly diminish the large number of compensation claims heard in the courts one, two, or even three years after the patient has been discharged fit for work from the hospital. The man returns to work sooner, knowing that if any residual pain and stiffness prove disabling he will be taken back by the hospital without prejudicing his compensation payments or his position with his firm.

At the Albert Dock Hospital considerable success has been achieved in obtaining the co-operation of employers, by means of which a man can be told that a job is waiting for him as soon as he is fit, thus removing from his mind at the commencement of physical treatment a very real obstacle to recovery. On one or two occasions men were so worried about debts incurred since their accident that all attempts to get them fit for work failed, and they seemed bound to join the ranks of the permanently incapacitated. The offer of a

sympathetic employer to settle their small debts and provide them with work caused a dramatic recovery, and a happy, competent workman was restored to industry.

There are very few true malingerers, and the number that deliberately seek compensation claims can be materially reduced by suitable psychological treatment. However, there is a serious danger to success from the touting agents of certain firms of solicitors. These hang around fracture clinics attempting to undermine the patient's confidence in the disinterestedness of the medical staff, and persuade him to put his "case" in the hands of the solicitors they represent. I have known patients to fall under the influence of these men immediately on arrival at the hospital, even before they have been seen by the doctor on duty.

In conclusion, may I suggest that the value of rehabilitation treatment is not confined to the recently injured. Old cases, perhaps of years' duration, with gross deformity, and apparently a permanent liability on the State, often do surprisingly well. The knowledge that at last someone is taking an interest in their "case," combined with the strengthening of muscles allowed to grow weak from disuse and the atmosphere of cheerful expectation of recovery that should pervade every rehabilitation clinic, will sometimes restore a hopeless chronic to partial or full work in a surprisingly short time. One or two of these cases in a year will handsomely repay a firm for any financial aid they give to the clinic or the injured workman.—I am, etc.,

G. R. BUTTERFIELD, F.R.C.S.Ed.,
Late First Assistant, Albert Dock Hospital
Fracture and Rehabilitation Clinic.

London, April 17.

Transfusion of Red Cells

SIR,—In the present emergency the frequent occurrence of shock in patients injured in air raids necessitates the maintenance of large stocks of plasma in blood "banks." When plasma is prepared the erythrocytes are usually discarded. It is apparently not widely realized that the red cells can be used effectively for raising the haemoglobin level in anaemic patients not suffering from shock. In fact, concentrated cell suspensions have certain definite advantages over whole blood for patients whose haemoglobin is low but whose blood volume is not reduced—for example, pernicious anaemia, aplastic anaemia, haemolytic anaemia, purpura, or post-haemorrhagic anaemia when the bleeding has stopped and the blood volume has been restored from the tissue fluids.

Since the volume of cells from 500 c.cm. of whole blood is approximately 250 c.cm., including the residual plasma (the exact volume depending on how completely the plasma has been separated), it follows that the rise in haemoglobin after the transfusion of a certain volume of cells is about twice that which follows the transfusion of the same volume of whole blood. Alternatively, to produce a given rise in haemoglobin it is necessary to transfuse red cells in only half the volume of whole blood required for this purpose. Accordingly, the transfusion can be completed much more rapidly with decreased risk of left ventricular failure and pulmonary oedema.

It should be pointed out that the red cells should be utilized as soon as sedimentation is far enough advanced for plasma separation—twenty-four to forty-eight hours after withdrawal of the blood, which is stored for this period at about 4° C. The cell suspension then contains the majority of the white cells and thrombocytes, and the residual plasma contains complement. Hence the suspension of red cells from a litre of blood has been found as effective in controlling haemorrhage as half a litre of fresh blood. It might be thought that a concentrated red-cell suspension of this kind would be more difficult to transfuse than whole blood and might involve increased danger of capillary blockage. Actually, we have not found this to be the case, using an efficient filter such as is supplied by most transfusion services. As a rule, however, we add about 100 c.cm. of sterile saline to the cells from each pint of blood; this reduces viscosity and the saline leaves the circulation before the transfusion is completed.

We have given transfusions of concentrated red-cell suspensions to many patients suffering from primary and post-haemorrhagic anaemia, invariably with satisfactory results. Single transfusions of red cells from two to five pints of blood have been given in one to two hours, the exact amount depending on the severity of the anaemia.

The object of this letter is to call attention to a method of transfusion which combines economy of blood with, in suitable cases, actual therapeutic advantages.—We are, etc.,

STANLEY DAVIDSON.
C. P. STEWART.

The University, Edinburgh, April 17.

Crush Injuries

SIR,—In common with your other correspondents I would like to congratulate the various authors for their work carried out in difficult circumstances on uraemia following crush injuries. There would appear to be a general idea that the syndrome has existed unobserved in civil practice, and pit accidents are put forward as a likely source. However, no instances have been cited since the articles appeared in the *Journal* of March 22, and I write to call attention to two cases published under the title of "Renal Lesions from Traumatic Shock," by Husfeldt and Bjering in 1937 (*Acta med. scand.*, 1937, **91**, 279). Both patients sustained fracture of the pelvis and damage to soft tissues. Shock developed in both, yielding to transfusion of citrated blood. Death occurred on the eighth day with a rising blood urea, hypertension, oedema (in one case), and general signs of uraemia. The urine was very scanty, of low specific gravity, and contained casts and a few erythrocytes. Renal function tests gave very low results. At necropsy no injury to kidneys or urinary tract was found. Microscopically the chief lesions were emptiness of the glomerular capillaries and degeneration of the epithelium of the tubules, in some of which granular-coloured pigment was present. Husfeldt and Bjering showed that incompatibility of blood could be reasonably ruled out in their cases by the preliminary tests, and further stated that the clinical manifestations and necropsy findings were not those characteristic of a fatality following a transfusion with an incompatible blood. In two of the cases reported by the M.R.C. Subcommittee in the *Journal* neither blood nor one of its derivatives was employed in treatment. This makes it improbable that one of these substances is responsible for the uraemic manifestations. In contrast to the air-raid casualties the duration of crushing was short—a matter of minutes rather than hours—and shock treatment was instituted soon after injury.—I am, etc.,

J. BASIL RENNIE.

Glasgow, April 15.

Limb Compression Ending Fatally in Uraemia

SIR,—With reference to the case of limb compression ending fatally in uraemia, which was especially reported in the *Journal* of March 22 (p. 434) by Drs. R. Mayon-White and O. M. Solandt because no blood transfusion had been given, I noticed that the child had had three transfusions of four-times-normal serum made from the pooled sera of Group A, B, and AB donors. I realize that the serum from AB donors is free from agglutinins, and also that serum taken from a mixture of A and B bloods may be practically free from agglutinins, but I see no reason to suppose that agglutinins are in any way lessened by mixing A and B sera after the agglutinogens in the red cells have already been withdrawn, as had apparently been done in this case.

It would appear to me that the serum used was possibly not free from agglutinins, and when given intravenously in concentrated form would be excreted almost immediately by the kidneys and might cause haemolysis of the recipient's red cells. This may be another explanation of the possible cause of "transfusion kidney" reported in so many cases of limb compression. I should like to know if serum and plasma are tested for the presence of agglutinins before being issued.

Crush injuries due to falls of roof are not uncommon in colliery districts; I have always treated them with rectal hypotonic saline and glucose as well as intravenous treatment, and I am wondering why more use was not made of rectal saline in the cases reported. These cases of anuria are apparently due to blockage of the renal tubules. It has occurred to me that dilatation of the renal tubules in an established case might be attempted by spinal or splanchnic anaesthesia.—I am, etc.,

J. T. RICE EDWARDS.

Newport, Mon., April 12.

Crush Injuries and Renal Failure

SIR,—In the cases of crush injury reported in the *Journal* of March 22 there is evidence to suggest that, whatever the mechanism, the result of the injury is to produce intravascular haemolysis. Many of the patients passed blood-stained urine soon after admission to hospital. Though jaundice has been reported so far the blood bilirubin in the case quoted by Beall, Bywaters, Belsey, and Miles was slightly raised.

Prof. Baker has shown[1] that post-transfusional urinary suppression is due to excretion of haemoglobin with a urine of high acidity and salt concentration. Under these conditions the excreted haemoglobin is converted to a granular deposit of haematin which obstructs the renal tubules. He also showed that, conversely, if the urine be alkaline no haematin granules are formed.

Thus it would seem that in these crush injuries more attention might profitably be given to the reaction of the urine, and that the aim of treatment should be to maintain an alkaline urine.—I am, etc.,

T. DINSDALE,
Surgeon Lieutenant, R.N.V.R.

March 29.

Blast Injury to Lung

SIR,—I should be grateful if you would allow me space to comment on certain matters of fact raised by Dr. G. R. Osborn (April 5, p. 506).

1. When a bomb bursts in a confined space reflections from the walls increase both the impulse of the blast wave and the time for which high-pressure values are sustained. Assuming that the walls are blown out, this increase in time is, however, only a matter of some thousandths of a second. On the other hand, if the force of an explosion is insufficient to break the walls in an "average" house (that is, if the explosion is a small one) the blast wave is reflected from wall to wall until its energy is absorbed and its pressure falls to that of the normal atmosphere. In the first case blast injuries would be of little clinical interest, since people in the room with the bomb would almost certainly either be killed or also suffer from severer injury due to agencies other than blast. In the second case it is unlikely that people in the room would be directly hurt by the blast, for, as both experiment and critical field observation have shown, if the pressure is insufficient to knock down walls of ordinary thickness and construction it would also be below the threshold at which lung damage occurs.

Dr. Osborn is misleading in treating a house in which an explosion takes place as a single unit. Lest his remarks about the extensive risk of the direct effects of blast in houses cause alarm, it should be stated that when a bomb of small or medium calibre bursts in a room so much energy of the blast is absorbed in shattering the walls that the pressure outside the room is as a rule relatively small, and relatively harmless from the medical point of view. This has been found both by experiment and by careful analysis of actual incidents in which people have been in rooms adjacent to one in which a bomb has burst and blown out the intervening walls. With all except the very heavy types of bomb, primary blast injuries are unlikely outside the room in which an explosion occurs or in open passages leading from such a room. Primary blast injuries in houses from bombs falling outside are only likely when the bomb is so big and the pressures so great that the houses are completely demolished.

2. Dr. Osborn states that there is "no justification" for my reported remark (*Journal*, January 18, p. 94) that at sixty or seventy feet the blast pressures in the open from a "large" bomb cannot directly harm even though they may be sufficient to damage walls and windows. Paradoxically, he also states that this view is usually true. The justification for the statement is that it is based on actual observation. It is not usual to publish the sizes of bombs. Nevertheless it can be stated that since it is necessary to multiply the charge eight times to double the distance at which a given pressure will occur (a law to which I referred in my paper to the Royal Society of Medicine[2]) the threshold distance for "primary-blast" lung injuries even for the largest bombs now occasionally used is unlikely to exceed, say, 150 feet in the open.

Human beings are very much more resistant to the primary effects of blast than are most building materials. Furthermore, in so far as an evaluation of the position is possible on the available facts it can be stated that, at the same distances and from the point of view of the direct effects of blast, a man in a room in which an explosion occurs is worse off than a man in the open; whereas a man in a room adjoining one in which an explosion occurs is better off than he would be in the open.

3. Not academic interest but practical need made it urgent to discover how blast exercises its primary effects on the body and to what extent its direct effects can be observed in air-raid casualties. We have taken no pains to belittle, as Dr. Osborn suggests we have, or to exaggerate the importance of, the problem. Owing perhaps to lack of knowledge of the circumstances under which his cases were injured, knowledge which Dr Osborn suggests is not only unnecessary but perhaps misleading, it is doubtful, as my colleague Dr. Krohn suggests below, whether Dr. Osborn's paper has in fact much to do with the direct effects of blast—except in so far as it speculates about the subject. His cases reveal no evidence of direct blast injury as the term should be used, and much evidence of more understandable forms of trauma due to secondary and tertiary effects of blast—violent displacement, falling masonry, and secondary missiles, any or all of which, as I have emphasized before, may cause lung injuries that in many respects resemble those caused directly by blast.[3] It is probably to such agencies mainly that most lung injuries in air-raid casualties are due. Whatever their cause, however, it is necessary, as Dr. Osborn points out, that their presence should not be overlooked.—I am, etc.,

S. ZUCKERMAN.

Department of Human Anatomy, Oxford, April 21.

SIR,—There can be no question that many varied forms of trauma to the thorax, as well as the blast from high-explosive bombs, can produce haemorrhagic lesions in the lungs without causing any obvious injury to the surface of the chest. It is also clear that, whether the direct action of blast, or falling on to a hard surface, or the impact of flying masonry is responsible for the injury in air-raid casualties, all three immediate causes depend on the explosion of a bomb. Finally, it is apparent that, however the lung injury is caused, the means of diagnosing it clinically and the methods of treatment are likely to be similar.

These general points Dr. G. R. Osborn rightly brings out in his article in the *Journal* of April 5 (p. 506). He appears, however, to deprecate attempts to look more closely into the matter, and *ex cathedra* suggests that, as a rule, blast plays a direct part in causing injuries to people removed from bombed buildings (presumably forgetting that explosions have not occurred in a very high proportion of what are called bombed buildings).

It is permissible to use Dr. Osborn's series of eight fatal cases to test this generalization. No details about external or internal injuries are available for one case. Of the remaining seven: Three had fractured skulls—one of these cases, a girl of 17, appears to be the same as that described by Osborne in a previous paper.[4] In the present account Osborn states that a fractured skull was the only external injury. In his earlier paper he refers to abrasions of the right hand. One had a fractured skull and fractured ribs. One had multiple injuries from secondary missiles, with a penetrating wound of the chest, and a forearm "blown off." One had multiple penetrating wounds, four of which perforated the skull, and four ribs were also fractured. One had a perforating wound of the chest.

Some degree of intrapulmonary haemorrhage was found in all but one of the seven cases (the exceptional case being one of the three with only a fractured skull). Of these six, four had either perforating wounds of the chest or fractured ribs. These obvious chest injuries (and falls or crushes probably associated with them) might well have been the cause of the observed intrapulmonary haemorrhages.[5] Clearly, too, the remaining two cases with fractured skulls must have suffered

[1] "Urinary Suppression following Blood Transfusion." S. L. Baker, *Lancet*, 1937, 1, 1390.
[2] Zuckerman, S., *Proc. roy. Soc. Med.*, 1941, 34, 171.
[3] Osborn, G. R., *British Medical Journal*, 1940, 2, 317.

violent external trauma, which, it is also known, may cause lung damage without any apparent external injury.

It is, of course, possible that part or all of the observed lung lesions may have been direct effects of blast. Since, however, this possibility must remain speculation, it is surely safer to suppose that the more obvious trauma to which the casualties were subjected was responsible for the pulmonary lesions, and that blast played only a secondary part, if any part at all.

Another point in Dr. Osborn's account which suggests this conclusion is the fact that Cases 1 and 2 were beside each other when the house they were in collapsed. The blast pressures sustained by these two casualties were probably identical, and while there is individual variation in the lesions caused by a given pressure, probably the most satisfactory explanation of the different degree of lung damage would be that the injuries were not due to blast acting on people of different physique, but to falling masonry or debris, the effects of which might well have been different for the two persons. It is particularly in this sort of case that the exact history of the incident, which is rejected as misleading by Dr. Osborn, would in fact have been of value—not perhaps to the clinician, for the patient soon died—but perhaps to the pathologist and experimental worker.

Furthermore, Dr. Osborn emphasizes the importance of the severe damage to abdominal organs which occurred in four of his cases. It should be noted that while about 40% of animals exposed to blast showed abdominal lesions these were usually only small patches of petechial haemorrhages in the intestinal wall; serious tears or ruptures of abdominal organs were rare.[2] Since the animals were undoubtedly blasted (in the sense that the term relates to explosions) and yet failed to show serious damage to the abdominal organs, it appears possible that the severe visceral lesions described by Dr. Osborn were not due to the blast but to the impact of a more obvious crushing agent.

Dr. Osborn remarks that lung injuries are "now only too common in hospital practice," even though the number of such cases reported already would seem to be remarkably small. The publication of detailed information concerning these cases would be very valuable and more likely to bring solution of the problems closer than speculation unaccompanied by experiment. It may be added that Dr. Payne reports in the *Journal* of April 12 that he has seen no blast injuries in a series of 226 air-raid casualties.

There are two methods which may help us to decide the importance of blast in causing injury. (1) Rupture of the tympanic membrane will often be present if the patient were close enough to suffer at all seriously from the effects of blast. The eardrums of air-raid casualties should always be examined. (2) While fat embolism does not appear to play any part in causing the experimental lesions due to blast,[2] there is evidence that it does so in cases due to direct trauma. Robb-Smith's simple and effective post-mortem test[4] for the presence of fat emboli may help to differentiate the two types of injury.

Some other issues raised by Dr. Osborn are perhaps treated more dogmatically than is justified at present. Thus the question of whether the haemorrhage into the lungs is progressive or not cannot be answered by a plain yes or no. Any haemorrhage in any part of the body may be arrested or may continue. There can hardly be more justification for saying that all haemorrhages will stop than for saying that all will be progressive. Moreover, while it is very likely that the pressure component of the blast wave is the important factor in causing injury, the physics associated with the sudden and extremely brief impact of a wave of high pressure on such a complicated system as the thoracic contents are anything but obvious. Dr. Osborn writes that "to understand the lesions described for blast in animals and man there is no need to assume that blast has any mysterious properties." Yet he refers later to "the peculiar behaviour of blast on houses." This is an unusual inversion of the more reasonable doctrine that, while we can often define with accuracy the effects of a given agent on inanimate objects, the responses of the human body to the same stimulus are generally more difficult to unravel.

Finally, surely Dr. Osborn does not really mean us to believe that in determining the severity of injuries "the state of the patient is probably of greater importance than the size of the bomb or the distance from it." Whether the bomb is 500 lb. or 50 lb., and the distance 50 ft. or 10 ft., a surely more important than being thin and naked, or obese and heavily clothed, at either of those distances.—I am, etc.,

P. L. KROHN.

Treatment of Burns and Scalds

SIR,—From the numerous letters that have appeared in the *Journal* recently on the treatment of burns, and from the number of local remedies advocated, one can only conclude that up to the present no local application has been found that can be safely recommended to the profession for the routine treatment of burns. Everyone seems to be agreed that tannic acid rightly applied—that is, after thorough cleansing of the skin—is probably the best remedy of all. But what appalling results one meets with after the indiscriminate use of that extremely excellent application tannic acid jelly, which is now to be found in every household!

The question arises, then, Is there any application that one can safely recommend in all cases? Almost more important still, Is there any application that one can safely recommend to first-aid parties? I believe that the only preparation that meets all the requirements, not only as a first-aid measure but also as a routine treatment of burns, is acriflavine emulsion, 1 in 1,000. I have used this preparation now for a considerable time to the exclusion of all other forms of local treatment and have never been disappointed. It possesses the following merits: it is safe, it is soothing, it is antiseptic, and healing takes places more quickly than with any other local application that I am acquainted with.—I am, etc.,

T. J. HOLLINS.

Battle, April 13.

Epidemic Gastro-enteritis

SIR,—The problem of epidemic gastro-enteritis, such as described in the report by Lieut.-Colonel A. H. D. Smith and Captain D. J. Davies (April 12, p. 554), is one which has confronted all general practitioners during the past winter, and the value of the report seems to lie in the negative bacteriological and epidemiological findings. As the writers state, these findings suggest perhaps a virus infection allied to influenza, or perhaps influenzal gastro-enteritis itself. Identical cases to those reported have been frequent this year, and the opportunity of observation in a military camp is valuable, since large numbers are not seen in general practice, nor are the opportunities of laboratory aids open to the busy practitioner.

The cases seen have shown many diverse symptoms, some of which are not mentioned in the report and which may or may not be related to the one infection, but at any rate they occurred in the same patient, either at the same time or more frequently preceded or followed on the gastro-enteritis.

The following appear to have been the main types: respiratory catarrh, bronchitis and pneumonia, vomiting and/or diarrhoea, epigastric discomfort and nausea, myositis and fibrositis ("muscular rheumatism," especially interscapular), neuritis (localized—e.g., supra-orbital or external popliteal), and low back pain chiefly affecting the sacro-iliac joints (this persisting for one or two weeks). Two patients developed joint swellings similar to acute rheumatism. In addition I have noted several cases of acute conjunctivitis of moderate severity, one case commencing with this and developing the gastric symptoms three days later. Almost all the patients had one constant feature—namely, redness and soreness of the fauces. All the cases seen cleared up rapidly, with the exception of those more severe respiratory affections, chiefly in the older patients. Several cases showed definite localized tenderness in the right iliac fossa and were difficult to differentiate from acute appendicitis, but the associated symptoms, and often accompanying tenderness over the epigastric region, were as a rule present. This appendicular tenderness, it is reasonable to suppose, was due to involvement of the lymphoid tissue in the appendix similar to that of the tonsils or fauces. In these cases among the general public the incubation period and infection by direct contact were noted to be similar to those mentioned by the writers of the report, but in some cases the contact developed the related, and not the identical, type of symptoms.

Finally, as mentioned above, the opportunity of pathological investigation presented in the military camp is valuable, and seems to stress the need for a medical service on the lines suggested earlier by Dr. S. Terry Pybus (*Supplement*, March 15, p. 29) in which central clinics and laboratories would give those opportunities of investigation at present denied to a busy general practitioner.—I am, etc.,

Brierfield, Lancs, April 14. H. C. PALIN.

Incubation Period in Cases of Gastro-enteritis

SIR,—Lieut.-Colonel A. H. D. Smith and Captain D. J. Davies (April 12, p. 554) give an interesting account of an outbreak of gastro-enteritis among troops.

I have seen forty-seven cases this winter with symptoms and signs as they describe. I have not the facility for examination of the stools in each case, but I have had negative reports in four cases. These observers put the incubation period at thirty-six hours to seven days. Many of the cases I have seen have had an incubation period of twenty-four hours. I have no recollection or record of any case in which it was longer than four days. In one family the father had been away on business and stayed with a family where the infection was in progress. He returned home one evening and was himself ill in the night. Exactly twenty-four hours after his return home one child took ill, and the other three persons in the house were all attacked within four days. These, of course, may have been infected by the husband or by later infected persons in the household. All had been inoculated with T.A.B. two months previously. This family history is almost typical.

I agree, too, with the sporadic distribution of the infection. I cannot narrow it down to contamination of milk or food.—I am, etc.,

Leeds, April 14. R. A. MURRAY SCOTT, M.B., B.Ch.

Digestive Disorders in the Forces

SIR,—I was very interested in the article by Lieut.-Colonel J. Gibson Graham and Captain J. D. Olav Kerr on digestive disorders in the Forces (March 29, p. 473). We do not fully understand the cause of peptic ulceration yet, but the stress and strain of modern life seems to be a predisposing factor in many cases. Hence it seems astonishing that men should be accepted for service who have had definite ulceration previously, not to mention haematemeses, perforations, and gastro-enterostomies.

Surely it is plain to see that a few weeks of Army life may undo perhaps years of treatment. As the authors point out, many of these men were able with care to carry out a normal and useful civil life. If such men are accepted they will rapidly be occupying hospital beds, be no use at all as soldiers, and have weeks of treatment in front of them before they are able to return to their civil occupation again.

It is to be hoped that medical boards will in future reject all who suffer or have suffered from this serious and painful complaint.—I am, etc.,

Sheffield, April 13. J. A. WOOD.

Obscure Nervous Effects of Air Raids

SIR,—I have read with great interest Mr. Tom Harrisson's letter on this subject (April 12, p. 573). If it could be arranged for these cases to be examined by a competent rhinologist I believe it would be found that all, or nearly all, of them were suffering from chronic sinusitis. The combination of concussion—whether blast or impact—with sinusitis seems to produce a *forme fruste* of encephalitis lethargica.—I am, etc.,

London, W., April 16. H. CRICHTON-MILLER.

Malarial Therapy for Epilepsy

SIR,—With reference to your annotation on the treatment of G.P.I. (March 29, p. 486), the late J. C. Ramsay (*J. ment. Sci.*, 1929, **75**, 257) treated with malaria at Claybury Mental Hospital six cases of epilepsy, four of which showed the haemoclastic crisis. Four patients showed a temporary reduction of fits with a subsequent increase during observation periods exceeding seventy-five days after the final malarial paroxysm. In two cases amelioration of the mental condition occurred.—I am, etc.,

April 2. G. DE M. RUDOLF.

Convulsion Therapy by Electricity

SIR,—Dr. James S. McGregor (April 12, p. 571) takes as the basis for his criticism of faradic shock therapy his own statement that this treatment was fully investigated in the nineteenth century. And a casual reader might be justified in assuming that in advocating it I am as culpable as if I had proposed to reintroduce the strait-jacket and the whip into psychiatric practice. But on closer investigation one soon realizes that the nineteenth-century methods were not identical with those described in my article. The details of Allbutt's technique, which Dr. McGregor describes, illustrate this point very well. Allbutt (1872) passed a galvanic current for ten minutes through the patient's head in order to obtain a "tranquillizing effect." This is surely quite different from the method that I described, the differentiating features of which are: (*a*) that the procedure is used as an aid to psychotherapy; and (*b*) that a period of psychological stimulation is produced by a series of short faradic shocks, followed by a period of depression produced by barbiturate anaesthesia. In fact the only similarity I myself can see between these two methods is that both make some use of electricity in the treatment of mental disease. And incidentally they have this point in common with the electric convulsion therapy which Dr. McGregor champions so ardently. Surely if we are going to follow Dr. McGregor in condemning faradic shock therapy because something vaguely similar was practised in the nineteenth century, we must also decry Berger's electroencephalography because Caton in 1875 showed that electrical changes occurred in the brain, and his work aroused very little comment.

I was interested to read Dr. McGregor's explanation of the method of production of the convulsion which I described. He says "it was possibly brought about by summation of subliminal stimuli." But the "subliminal stimuli" were applied at intervals of twenty-four hours, and summation is generally not supposed to occur if the interval is longer than twenty-thousandths of a second. So I feel that in making this suggestion he is taking up rather an unorthodox attitude to the accepted views on the physiology of the nervous system.

As for Dr. McGregor's allegation that my statements regarding the dangers of convulsion therapy were "unwarranted" and "misleading," it seems that he wrote his letter without bothering to consult the four references which I gave in support of those statements. And also it is apparent that, although he is so well acquainted with the West Riding Lunatic Asylum Medical Report for 1872, he is unfamiliar with the issue of the *Journal of Mental Science* for 1941 (p. 230) in which Cook and Sands give eleven references to papers on spinal fractures resulting from convulsion therapy. I envy Dr. McGregor his good luck in having induced 1,800 major fits without the occurrence of any complications. But at Winson Green Hospital we make a routine radiological examination of every patient before and after a course of convulsion therapy, and I am sorry to say that out of 101 patients, with 1,015 convulsions, we have had 21% of cases of fractured vertebrae. A more detailed account of these facts is in preparation for publication.

Finally, I must refer to the only valid criticism contained in Dr. McGregor's letter—namely, that faradic shock therapy is rather painful and unpleasant to the patient. I am of the opinion that it is no more unpleasant than chemical convulsant therapy, but some patients certainly do become apprehensive and express their dislike for the treatment in no uncertain terms. However, the unpleasantness *per se* cannot be regarded as a contraindication to any treatment, otherwise we would have to veto a large number of the routine manipulations of surgery. The important factor in every case is the therapeutic efficacy of the treatment, and if the results are good enough they may well justify a degree of unpleasantness far exceeding that of faradic shock therapy.

In conclusion, I would say that at the present time our ignorance in this field of shock therapy far outweighs our knowledge. We do not know how the convulsions are caused, we do not know why they produce therapeutic results, there has been no final evaluation of those results, nor do we yet know all the dangers of the treatment. This being the case, every investigation is welcome which attempts to throw light on the problem. And the results of such an investigation should be criticized in a scientific manner, in order to distil from them whatever small particle of truth they may contain. —I am, etc.,

Birmingham, April 15. GERALD CAPLAN.

Treatment of Scabies

SIR,—The aetiological agent of scabies is the itch mite, or acarus. The acarus lives upon the skin, which is penetrated only by the female parasite. The male dies after copulation and the female after the ova (fifty in number) are laid. In four to eight days the larvae are hatched and the cycle from egg to adult takes seven to thirteen days.[1] The ova are laid in burrows in the epidermis, and the larvae on hatching bore into the sides and floor of the main burrow.

The parasiticide must be brought into contact with the ova, larvae, nymphs, and parasites, or these must be removed mechanically in order to effect cure. This is materially assisted by using a soap, such as soft soap, with an oleate or stearate of potash, which is a strong keratolytic.

The classical treatment of scabies uses sulphur as the parasiticide, but opinions vary as to the strength to be employed. Roxburgh[1] advises 5 to 10%, Andrews[2] 10 to 15%, and Hoffmann[3] 25%. The customary course takes three days. Modifications of the sulphur treatment have been used, such as mitigal and kathiolan. The treatment with sulphur has in recent years been to some extent superseded by benzyl benzoate (a distillate of balsam of Peru). The benzyl benzoate is prescribed with equal parts of soft soap and isopropyl alcohol. A course of this treatment takes twenty-four hours. A rotenone preparation has recently been put on the market. This treatment requires two and a half days.

The aim in the treatment of scabies is the achievement of cure in the shortest time possible without the production of dermatitis medicamentosa. It is an established fact that sulphur will produce dermatitis, but this should not occur if the treatment is limited to three days. It is claimed[4] that the benzyl benzoate treatment, lasting for one day only, is free from the danger of dermatitis, and it was hoped that similarly the rotenone preparation would not cause irritation in the two and a half days required for treatment. In my own experience I have found that sulphur will produce a cure in three days, and that with few exceptions there is no following dermatitis. In the case of the rotenone preparation, however, two and a half days' treatment appears almost invariably to give rise to dermatitis. Benzyl benzoate treatment if limited to twenty-four hours is apparently free from following dermatitis. I am not satisfied, however, that a cure is achieved. The reason for this statement is that I cannot conceive, nor have I found in practice, that all the ova, larvae, nymphs, and parasites are reached by the parasiticide. As the larvae are in subsidiary burrows running from the main burrow, it seems to me impossible that all these subsidiary burrows are opened up and all the larvae killed. If some larvae remain untouched they will mature, and only if treatment is continued will they in their turn be killed. It is not the strength of the parasiticide that is important but its power of penetration. I believe that it would be illuminating to compare a series of cases treated with benzyl benzoate with one treated with sulphur, both over a period of twenty-four hours.

In conclusion I should mention that any twenty-four-hour treatment must be very thorough, and the preliminary bathing and breaking down of burrows must be effectively carried out. This appears to me to be difficult of attainment in ships at sea. On the other hand, any three-day treatment, depending to some extent on the maturing of the parasite, does not necessarily have to be so carefully done, nor is the bathing of immense importance. This type of treatment is, I feel suitable for use at sea.—I am, etc.,

National Wheatmeal Bread

SIR,—There is to be found in this week's *Radio Ti* excellent half-page advertisement of the virtues of the grain flour. It is brief; it is non-technical; it is written: it is issued by the Ministry of Food. It end the words, "Order it from your baker." How encou when advertisers recommend to our people their an food and not the output of the patent medicine facturers. But how disappointing to find that the ba not "playing," for a tour of the bakers' shops aski national wheatmeal bread and quoting the Ministry of produced answers thus: (1) I am not baking this loaf; (brown loaf is practically the same; (3) There is no d for this. So now what? Is a good piece of public work to fail through non-collaboration at the retail end A little judicious canvassing by the profession would to be indicated here: a few kind words to the local b and in the houses of the patients a certain disapproval o mass of meaningless starch—the white loaf; a suggestio what was, until recently, the traditional food of E is a source of well-being and very pleasant to eat.—I am,

Henley-in-Arden, April 15. R. G. HOD

An Unusual Case of Diphtheria

SIR,—One of us (M. G.) was called out to a child, ag months, suffering from a "sore mouth." It had a tempe of 99.8°, and on examination a sore-looking sloughy patc seen surrounding the right central and lateral incisors. throat was absolutely clear. The patch did not look theritic, the face was not greyish, and there was, ir nothing about the case to suggest its true nature. The were discoloured at the point where the condition app to have started, which was not surprising, as the child been artificially fed and was somewhat rickety. The con was obviously not thrush, and a tentative diagnosis of Vin angina was made. Sulphapyridine was given, as it wa that the child was rather young for nicotinic acid. The condition improved markedly and the patient was obvi much better.

The case was so unusual and the appearance so unfan that the other of us was called into consultation. We unable to make up our minds definitely, although we felt that it must be either a Vincent's angina or an exte of some infection, probably streptococcal, from the mentioned. At this time the patch was roughly circular half an inch in diameter. It lay both behind and in fro the teeth. Diphtheria was considered, but, despite the gestive temperature, the general picture and the age of the virtually ruled it out. The same applied to thrush, the app ance alone settling the matter. We sent a swab from the sl to the county pathologist for examination, and were astoni to find that it yielded a pure culture of *B. diphtheriae*. further careful search was made for signs in the throat, there was nothing beyond a slight deepening of the usual colour. The child was given 20,000 units of antitoxin, and improvement which it was already showing on sulphapyri was much accelerated.

Neither of us is aware of another case like it; but we facilities for a search of the literature. We think that unusual site, the fact that it is the only case in a small t which was most thoroughly immunized by the County Med Services only last year, and that it was so atypical in appe ance make it worth recording. We see a fair amount diphtheria, much of it not typical, and we swab all thro in which there is any suggestion of a membrane or of follicu spots larger than the usual, however unlike diphtheria t may be. As the negative cases are usually streptococcal give sulphanilamide (or sulphapyridine if we think there mi be danger of pneumonia) in those which we judge to be diphtheritic, and antitoxin to the rest. Occasionally we wrong; but we have found that the drugs mentioned ha such a powerful curative effect on true diphtheria that when

get a positive diagnosis over the telephone the case is so much improved that we give antitoxin more as a matter of conscience than as a necessary remedy.—We are, etc.,

ANDREW KEFALAS, M.A., M.B
MAURICE GOLDIN, M.B.

Blaenavon, Mon.

Repair of Lacerated Eyes

SIR,—I read with great interest the paper by Mr R. Lindsay Rea (April 12, p. 555). The author of this ingenious operation is not Kuntze but Kuhnt. The success depends upon the flap of conjunctiva being not perforated. If the conjunctiva is torn, the bridge may be prepared with the base only being adherent, the top being free and being fixed to the raw or roughened wound of the eyeball. During the last war, in the Russian Army, I often had to operate on eyes where no conjunctiva was available or the conjunctiva was in a bad state as a result of trachoma. In my desperation I tried a free flap from the mucosa of the lips of the patient, carefully cutting away all fat and leaving only the mucosa and submucosa. The result was excellent and no infection followed. The submucosa surface, of course, is to be applied to the wound.—I am, etc.,

London, E.1, April 13. N. PINES.

Medical Planning Commission

SIR,—In this Division during the past months much time has been spent and will continue to be spent in general meetings of the profession and meetings of subcommittees in discussing the future of medicine. All members of the profession are invited to participate. By this means our knowledge and experience of the problems concerned are enlarged and our views are crystallized; we are in close touch with our local representative on the Planning Commission, who is thus kept informed of the opinions of his particular community, and it is proposed to submit any memorandum which may be drawn up as the result of our deliberations to the Commission and to publish it more widely. Apart from the benefits which we derive from these deliberations, and which we may be able to pass on to others, we feel that we are doing something to clear the ground for later action when those of our colleagues who are now away on Service return.

My committee has requested me to make this communication so that others—and especially those who are away on Service—may know that some constructive as well as destructive work is being done, and we have no doubt that similar work is being done in many other Divisions. The place of British medicine has always been high and in many respects unique. It is the responsibility of every member of the profession to contribute his part towards ensuring that changed social and economic conditions do not find us unprepared. There is such an abundance of work to be done that too many cannot be engaged upon the discussions and deliberations essential to the achievement of the best medical services.—I am, etc.,

JOHN T. INGRAM, M.D., F.R.C.P.,
Chairman, Leeds Division, B.M.A.

Leeds, April 15.

SIR,—The Chairman of the Council stated (April 12, p. 569) that the work of the Planning Commission will be tested as it proceeds "and the views of the Divisions and Branches will be invited before coming to any important conclusions." For this purpose it would be very useful if a summary of the data which the Commission and its committees use could be published in the *Journal* as soon as possible after they have been considered. This would give members time to weigh the evidence before meetings of Branches are held, and it would enable them to send to the Commission some information which might not otherwise reach it. The *Journal* might not be able to publish correspondence arising out of the summaries, but members would have a real chance to test the Commission's work by considering slowly—not hurriedly—the same evidence as the Commissioners.—I am, etc.,

London, W.1, April 15. J. M. ALSTON.

SIR,—In the weekly space devoted to the Medical Planning Commission it is a relief to note an increasing emphasis upon detailed suggestions likely to be helpful to the Commission as actually constituted. The Commission will, I feel, enjoy the fullest confidence of the profession as soon as its *modus operandi* is seen to be elastic and not hide-bound by precedent and tradition. Mr. H. S. Souttar in his reassuring letter (April 12, p. 569) voices the need for the fullest possible criticism of the Commission's findings whenever and however these come to be divulged; but he assumes too readily, in my opinion, that the ultimate submission of these findings to various branches of the profession and to B.M.A. Divisions will provide adequate discussion and consideration. The experience of many members with regard to two pre-war "reforms" does not bear this out: three years ago, over both the "Medical Service for the Nation" plan and the subsequent proposals for limited panels for medical aid in childbirth the profession as a whole was presented as nearly as possible with *faits accomplis*. In the former case the main details of the scheme were first seen by many doctors through public advertisements in the *Radio Times*, while in the latter the frantic eleventh-hour discussion which centred around "Ministry of Health Circular 1705" made it quite clear that the rank and file of medical practitioners felt they were being "sold," and in this they were loyally supported by their colleagues specializing in obstetrics and gynaecology. So much, then, for that method; it is unpopular here.

I feel strongly that the numerous complex problems raised by the present situation require the fullest possible ventilation in the light of day *before* any concrete proposals are put forward as well as afterwards. To say "the views of the Branches and Divisions have been fully consulted and are in agreement on all major points, etc.," is all very convincing in theory and, on paper, looks the height of democratic form and thoroughness; in actual fact, as a little anamnesis concerning the average B.M.A. Branch meeting on any vital issue will reveal, such a procedure is the very reverse of thorough. Need we so hastily condemn "the pathetic suggestion of a questionary"?

Without trespassing too freely on your valuable space I should like here to give vent to my own personal fears regarding the pitfalls of a State Service. I feel there is a real danger that all the bureaucracy of the present public health services will tend to be incorporated. Let me quote two examples: (*a*) Under the present E.M.S. arrangements surgical cases are transferred daily, often at an hour's notice, from beds in the voluntary hospital to a near-by municipally controlled hospital; yet, from this municipal hospital these same patients cannot be sent home for at least twenty-four hours after I have discharged them as fit. (*b*) Under the existing "inefficient" system, soon to be consigned to the museum of antiquities, a practitioner or surgeon is accessible, in person or by deputy, to all his patients for twenty-four hours a day and seven days a week untrammelled by a single inch of red tape. In many of the public medical services which have already invaded spheres of private practice the week-end and the bank holiday are as sacrosanct as in any shop or office, and—this is the vital point—but for the collateral operation of the old and tried "G.P." system the shortcomings of the newer service would have been more apparent than hitherto.

Finally, I think that the Commission as at present constituted and without access to *all* possible shades of opinion will tend to organize the new health services from specialist downwards instead of from the lowliest practitioner upwards. Let, therefore, our watchword be: "Seek ye first" the keen, observant clinician, unhampered by even as much bureaucratic control as under existing N.H.I. arrangements, with far better pay than under the present panel system (or, at any rate, with regional discrimination should capitation fees be adopted), a minimum of unessential clerical work and a maximum of opportunity for extending his knowledge and for applying his wealth of clinical material to scientific advancement; consummate this product of 3,000 years of patient evolution in every corner of the globe, the general practitioner; and you need have no fear for your hospital policy, your consultant and public health services, for "all these things shall be added unto you."—I am, etc.,

Huddersfield, April 14. W. E. THOMPSON.

SIR,—I believe that some of your correspondents are unduly disturbed about the high proportion of "consultants and specialists" appointed as members of the Medical Planning Commission. It has been my experience, acquired, I must

admit, very largely in the United States, that efforts to raise the standards of quality in medical care have usually come from men who have specialized. And the first consideration in planning the medicine of the future is that the quality of care shall be improved. This is the peculiar contribution which our profession is qualified to make. The administrative and economic aspects of medical care will, whether we like it or not, be largely determined by laymen. Since good medical care cannot be cheap, it will be an important function of your Commission to inform the public on the prerequisites of good care: the importance which we attach to hospital and laboratory facilities, and the need for every doctor to have access to these and to the opinion of his colleagues who have specialized whenever he feels such an opinion to be in the interest of his patient. Also we must insist on the importance of medical research.

I heartily agree that the younger members of the profession should be represented, since they have the greater stake in the future of our profession. If they are not adequately represented on the Planning Commission it is only reasonable to suppose that they will form their own organization and present, if they feel it necessary, their separate recommendations.—I am, etc.,

Delmar, New York, March 4. J. ROSSLYN EARP.

Safeguarding the Medical Services

SIR,—The maintenance of the medical services is of greater interest to the nation than is the welfare of individual practitioners. Only when the cumulative effect of an increased number of individual disasters threatens to jeopardize the efficiency of the services will the Government find reason for concern. In such case, what more natural course could it follow than take the whole profession under its wing and form a national medical service? The profession, in straits, would have little power to dictate terms.

Is it not the duty of those of us who have suffered little from the ravages of war to see to it that the position of the individual members of our profession is so secured that such a calamity becomes impossible. The steps so far taken to this end have been dictated by the experience of the last war, when it was discovered that absentee members suffered loss to the benefit of those who stayed at home. These measures have, for a variety of reasons, among which may be mentioned bombing and the migration of populations, come short of expectation. Some home members, for whom no provision has been made that is not subject to the haphazard of coincidence or accompanied by the stigma of charity, have suffered even greater loss than absentee members.

In this unprecedented situation the threat to the effective running of the medical services must be met with unprecedented, even novel and revolutionary, measures. The immediate threat is to individual members of the profession. But the maintenance of their welfare is as essential to the medical services as the care of the soldier is to the prowess of the battalion. As this is a matter in which the Government is interested, a claim to their co-operation in the following scheme is not unreasonable. The suggestion is briefly: That a demand for an additional percentage of his income-tax payment be made to each member of the profession (it does not seem likely that it will need to be a large one); that this additional payment go to the formation of a fund; that from this fund payments be made to medical men whose incomes, *ceteris paribus*, have fallen below a certain percentage of their pre-war incomes—say, below a half—to raise them to two-thirds (with certain limitations) or, alternatively, to ensure to each member a subsistence.

Such a scheme has the virtue of: (1) Being simple, unerring, and fair in its exaction of tribute. (2) Calling for no casuistry on the part of the home practitioner in determining between *meum* and *tuum* in his relationship with the absentee practitioner. (3) Affording more prospect than the present arrangement of a livelihood to the absentee on his return, and giving it to the home practitioner also (the retention of practices being dependent now not only upon the attitude of patients but also upon their migration). (4) Covering all grades of the profession—consultants, specialists, G.P.s. (5) Making more easy the transfer of anyone to the E.M.S., whether that transfer become necessary through national emergency or personal straits. (6) Abolishing the humiliation of receiving charity. (7) Protecting the profession from an impoverishment that might make it (or, at any rate, many of its members from necessity and others from commiseration) too ready to accept a national medical service that meets the requirements of an oligarchy of statisticians rather than the taste of the public and the profession itself. (8) Compensating the Government, via the Exchequer, for the clerical work entailed through the extra income it gathers from the taxation of the amounts allocated.—I am, etc.,

Glasgow, April 18. W. MELVILLE CHRISTIE.

Medical Man-power

SIR,—With reference to your leading article (April 12, p. 559) dealing with the very important question of our decreasing medical reserves, might I suggest that pooling of the talents of medical men and women in the civil and fighting Services is often possible, and that this would go a long way to solving our difficulties.

Fully and partially mobilized medical units are often stationed for considerable periods in the vicinity of towns with large and under-staffed civil hospitals. These units, comprising many hundreds of medical men, are for the most part in reserve and not functioning in a medical capacity. Their officers, separated from clinical work, tend to become bored, and, with the passage of time, their efficiency suffers. If they were temporarily attached to civil hospitals they would supply a pressing need and at the same time maintain unimpaired their clinical capacity. A few officers would have to be retained at their units for administrative purposes; the training of the medical personnel as a whole could be kept up by short concentrated courses, and their services lent when not so engaged.

A major objection to such a procedure might be that such units must be prepared at short notice to proceed to a theatre of war. Such a difficulty could be overcome by other units in the process of formation taking over the civil functions of their predecessors, or, where this is not possible, a pool of senior medical students could be on tap to fill the junior vacancies during the period of transition.

Doubtless there are many other ways in which co-operation could be effected, but the procedure outlined above, owing to the large numbers of medical personnel involved, should prove important.—I am, etc.,

Hatfield, April 14. H. L. DUNN.

Nurse Anaesthetists

SIR,—Mr. F. MacG. Loughnane (March 22, p. 463) has upheld the nurse anaesthetist. Surely, without any adverse criticism of the nursing profession, to hail the advent of the nurse anaesthetist to the hospitals of this country is a retrograde step. The calling of the anaesthetist specialist is an essential one. Those who have seen the tragedies and the difficulties which result from the badly administered anaesthetic, the tired anaesthetist flustered and perspiring, know that for the safety of the patient and the smooth working of the theatre the expert is an essential. I have found that the better the surgeon the greater the recognition given to the anaesthetist.

The surgeon's income is not derived alone from the operations he performs, but from consultations, examining students and graduates for higher degrees, arbitration on accident cases, etc. The anaesthetist who gives his whole time to his specialty has only the private anaesthetic from which to derive his income, and is lucky if he can claim one-tenth of the surgeon's operation fee. In many cases the necessity to augment the income by private general practice is the sole reason why the anaesthetist cannot undertake all hospital work.

The answer is that if anaesthesia is to be efficiently undertaken in hospitals the hospital authorities must pay the anaesthetist a reasonable salary, not £20 or £50 a year, as some do. The anaesthetist can then give his whole attention to his very important work; not only important to the patient, but also to the student, who so often learns to anaesthetize by his mistakes rather than by the advice of his teacher, and the surgeon, assistant surgeon, and clinical tutor would have a "real necessity", and not a "luxury" as Mr. Loughnane terms the specialists in anaesthetics.

Milton treatment of wounds

This treatment proceeds by three stages:—

1. MILTON 50% SOLUTION

Thorough cleansing and mechanical removal of all infected plasma proteids, necrotic tissue and pus. Milton (up to 50% solution) dissolves this detritus and rapidly sterilises the clean surface. As a hypertonic saline it produces profuse fluid exudation.

> *"The process of mechanical cleansing is of "most advantage in wounds containing sloughs "and is well served by solutions containing "chlorine or liberating oxygen, both of which "tend to disintegrate and detach necrotic "tissue."—Lancet, May 4, 1940.**
>
> *"The most rapidly acting antiseptics are the "halogens and those liberating nascent "oxygen."—Lancet, April 27, 1940.**
>
> *"Profuse fluid exudation can be deliberately "produced by applying hypertonic solutions "of salt."—Lancet, May 4, 1940.**

2. MILTON 5% SOLUTION

The clean wound is kept sterile by an isotonic antiseptic protective layer, applied by dressing, irrigation or immersion. In this mild aqueous medium a normal granulation proceeds and exudation ceases.

> *"The proper vehicle for an antiseptic to be "applied to a wound is water, and the solution "should if possible be rendered isotonic."—Lancet, May 4, 1940.**

3. MILTON ½% SOLUTION

The Milton is then reduced to ½ per cent., at which dilution the hypochlorite has been found to actually stimulate cell-division and tissue-growth, with consequent rapid healing. After débridement, this course of treatment is normally painless.

This therapy cannot be carried out with full success by the use of Dakin's solution or of Liq. Sod. Chlorin., owing to their causticity, their deficient saline content and to their varying strength of hypochlorite.

THE TREATMENT OF INFECTION IN WOUNDS BY SULPHONAMIDES

ORAL ADMINISTRATION AND TOPICAL APPLICATION

Great attention has recently been attached to a form of topical sulphonamide therapy in which a relatively large amount of the compound is placed inside a wound and allowed to remain there.

The clinical and experimental data available on the subject is at present inadequate for the proper evaluation of sulphonamide implantation, but articles already published in the medical press clearly show that it is not a procedure which can be dismissed without further consideration.

We have prepared a memorandum summarising the data at present available on the subject and presenting a critical review of the position. We will be pleased to send a copy to you on request.

DAGENAN—M & B 693, *THIAZAMIDE, & SULPHANILAMIDE (MAY & BAKER) are now available in powder form for implantation. The container of 15 grammes is considered to be the most suitable for topical therapy.

SUPPLIES:

DAGENAN—M & B 693 (SULPHAPYRIDINE)	*Containers of . . . 15 grammes 4/-*
THIAZAMIDE (SULPHATHIAZOLE)	*Containers of . . . 15 grammes 6/6*
SULPHANILAMIDE (MAY & BAKER)	*Containers of 6 x 15 grammes 7/-*

Prices subject to the usual discount.

In the operating theatre the patient comes first. It is the patient's life which is in danger, so often from the anaesthetic and so seldom from the operation, and good anaesthesia is essential. An anaesthetist should be able to administer every type of anaesthetic, take charge of the patient should any incident arise, and should, in my opinion, feel competent to open the abdomen in order to carry out cardiac massage if need should arise. There are "ear and throat" and "eye" surgeons who, on their own admission to me, have never opened an abdomen, and ear and throat operations have a way of causing respiratory difficulties on occasions. To be competent to do this is asking a great deal of a young doctor and too much of any nurse. Anything less than this competence would tend to lower the already too slow increase in prestige which is due to the specialist anaesthetist.—I am, etc.

April 2. A. M. DUFF, Lieut.-Colonel, R.A.M.C.

SIR,—May I add one more opinion in favour of nurse anaesthetists from the surgeon's point of view. In America two years ago I had an opportunity of watching carefully the administration of anaesthetics by nurse anaesthetists in some of the most important surgical clinics there. The skill and efficiency of these technicians were remarkable. I have not seen in any European country such an all-round high standard. The objection to the present system in Great Britain and Ireland has been partially referred to by Mr. F. MacG. Loughnane (March 22, p. 463), where he stated that anaesthetists should attend at every hospital operation list. What about emergency operations, which frequently demand the greatest skill on the part of the anaesthetist as well as the surgeon? It was a rather uncommon occurrence in my student days—and probably is to-day—to see the official anaesthetist attending for emergency operations. It was found on those occasions that the house-surgeons could "carry on," yet on the mornings following, when the anaesthetist was in attendance, the house-surgeon had apparently lost the inspiration which Providence had bestowed on him the previous evening when it was not convenient for the anaesthetist to attend.

There are few branches of medicine more important and certainly none more neglected than anaesthetics. The position is bad enough in teaching hospitals, but is worse in hospitals situated in small centres like the county hospitals in Ireland, where, in many cases, the administration of anaesthetics is the *duty* of house-surgeons, who may be newly qualified, untrained doctors. I, personally, have performed operations with a doctor as anaesthetist who had never given an anaesthetic previously. I can go further and state that patients have died at operation, and I did not feel too sure that death was not due to an overdose of anaesthetic. The latter is a very difficult thing to prove, and no doctor wants to prove it. This system, it will be observed, is permitted in local government hospitals in Ireland, where the standard of anaesthesia is exceptionally poor.

Whatever may be said by doctors against nurse anaesthetists, I think few of us would voluntarily agree to an operation on ourselves with an untrained doctor giving an anaesthetic; on the other hand, few of us who have seen these technicians work would refuse an anaesthetic at their hands. There is an obvious economic difficulty in appointing doctors as anaesthetists to every hospital, particularly in small centres, but it seems to me that the sooner nurse anaesthetists are appointed in every hospital, with or without a doctor anaesthetist, the better for our patients and public health; we shall have far less "post-operative complications" and a reduction in "operative mortality."

I congratulate the Board of Addenbrooke's Hospital on their enterprise in appointing nurse anaesthetists; their action will be welcomed by the great majority of surgeons who, like myself, have not the "luxury" of special anaesthetists. None of us will deny the need for special anaesthetists and for research work in anaesthesia in suitable centres. The appointment of nurses who are competent to give anaesthetics will not hinder progress. On the contrary, it will produce a far wider use of several anaesthetics available to-day (but which we do not use); it will supplant the present deplorable system in many of our hospitals; and provide surgeons and patients alike with an essential now long overdue.—I am, etc.,

Croom, Co. Limerick, April 3. J. F. O'CONNOR, F.R.C.S.I.

The Services

COLONEL COMMANDANT, R.A.M.C.

Major-General H. P. W. Barrow, C.B., C.M.G., D.S.O., O.B.E., late R.A.M.C. (ret.), has been appointed Colonel Commandant, Royal Army Medical Corps, from August 27, in succession to Major-General R. S. Hannay, C.B., C.M.G., D.S.O., late R.A.M.C. (ret.), who has attained the age limit.

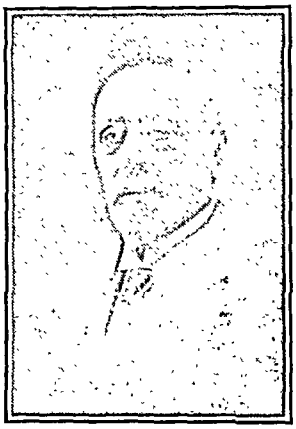
Captain Charles Westland Greene
Captain H. C. Rogers.

DEATHS IN THE SERVICES

Colonel THOMAS BOSWELL BEACH, C.M.G., C.B.E., late R.A.M.C., died at Reading on April 3, aged 74. He was born at Brompton on May 28, 1866, the elder son of the Rev. Canon W. R. Beach, Chaplain to the Forces, and was educated at Bloxham and at King's College Hospital, where he gained the Warneford Scholarship and worked under Lister. He took the M.R.C.S., L.R.C.P. in 1889 and, after serving as house-physician at King's, entered the Army as surgeon in 1891, passing first both into and out of Netley. There he gained the Herbert Prize allotted to the best man of the term and the Montefiore Medal and Prize for Military Surgery. He became lieutenant-colonel in 1912, colonel in 1915, went on half-pay in August 1919 and retired four months later. He served in the South African War in 1899-1902, when he took part in the advance on Kimberley, including the actions at Belmont, Enslin, Modder River, and Magersfontein; and in operations in the Orange River Colony, including the actions at Paardeberg, Poplar Grove, Driefontein, Vet River, and Zand River; in the Transvaal, in the actions at Pretoria, Johannesburg, and Diamond Hill; and in Cape Colony. He was mentioned in dispatches in 1901, received the Queen's medal with seven clasps and the King's medal with two clasps, and was promoted major. In the war of 1914-18 he was mentioned in dispatches in 1916 and received the C.M.G. in the same year and the C.B.E. in 1918, after serving as A.D.M.S. at Alexandria. He had been a member of the British Medical Association for fifty years.

Lieut.-Colonel AUSTIN ROWLAND O'FLAHERTY, R.A.M.C. (ret.), died at Westward Ho! on April 8, aged 71. He was born on February 7, 1870, received his medical education at the London Hospital, and took the L.S.A. in 1897 and the M.R.C.S., L.R.C.P. in 1901. Entering the R.A.M.C. as lieutenant in 1898, he became lieutenant-colonel in 1915, and retired in 1921. After his retirement he was for many years in practice at Torrington, Devon, where he was surgeon to the cottage hospital and a member of Great Torrington Borough Council, serving as mayor in 1927-8. He served in the operations in Sierra Leone in 1898-9 (medal with clasp); in the latter part of the South African War in 1902, in operations in Cape Colony (Queen's medal with three clasps); and in the war of 1914-18, when he was mentioned in dispatches in 1917. He had been a member of the British Medical Association for thirty-nine years and was chairman of the Barnstaple Division in 1929-30.



Lieut.-Colonel PERCY HILDEBRAND COLLINGWOOD, R.A.M.C. (ret.), died at Bristol on April 11, aged 60. He was born at Deesa, India, on April 2, 1881, received his medical education at St. Thomas's Hospital, and took the L.S.A. in 1897. Entering the Army as surgeon lieutenant in 1898, he became lieutenant-colonel in 1915, and retired in 1922. He served in the Nile campaign of 1898, receiving the medals and the Egyptian medal, and in the operations in 1903-4 in the Aden hinterland, where he was senior medical officer. He had been a member of the British Medical Association for seventeen years.

We have received from Messrs. Davis and Orioli, 1, St. Martins Street, Wallingford, Berks, a copy of their catalogue (No. 98) of historical books on genetics, evolution, and heredity, from the collection of Prof. R. C. Punnett, F.R.S., who has lately retired from the chair of genetics at Cambridge.

Obituary

PROFESSOR M. HAJEK

Prof. Markus Hajek, the famous laryngologist, whose death at the age of 79 we announced on April 12, was one of the most popular figures at international congresses, and one of the most popular teachers in the medical world. When, after having attained the legal age limit, he had to resign his clinical position, a special volume of the *Monatsschrift für Ohrenheilkunde*, etc., was dedicated to him; it contained 150 contributions by authors all of whom were former pupils of Hajek. The following appreciation is from the pen of a British colleague:

With the death in London of Prof. Hajek there passes the last of the professors of laryngology who made Vienna the Mecca of that specialty, ever since Türck in 1858 demonstrated the clinical application and value of Garcia's invention of laryngoscopy in 1855. Türck instructed Morell Mackenzie in the new art, and his beautiful album of water-colour drawings of the laryngeal conditions it rendered visible were piously shown to successive generations of students down to our own days. He was succeeded by such pioneers in the art as Schrötter, Stoerck, and Chiari. When the two chairs of laryngology were amalgamated with the two of otology—made famous by the work of Politzer and Gruber—one of the clinics of oto-laryngology was put under the direction of Hajek and the other under the popular and successful Neumann, who died recently in New York, also, like Hajek, an outlaw and an exile from their beloved Vienna.

In the nineties of last century Hajek began his career as assistant in the Poliklinik to Schnitzler, whose daughter became his devoted wife. His brother-in-law was the well-known dramatic author Arthur Schnitzler. It was at the Poliklinik that Hajek laid the basis of his life's work, by making the beautiful dissections of the anatomy of the nose and accessory sinuses which he demonstrated to his large class of students, often composed of numbers of English and Americans. Zuckerlandl's classical work on nasal anatomy, and Onodi's atlas of the same subject, had then been published, and these works and Hajek's teaching were the principal factors in spreading the knowledge of this region of the body, which until the end of last century had been only incompletely explored. Hajek, in his lectures, did much to demonstrate the clinical importance of personal and direct acquaintance with the anatomical arrangements and the frequent irregularity of this region, where danger and disaster are so ready to attend any mistaken route or any intrepid interference. His class was held at 8 o'clock in the morning, and was always full. It was followed by his clinic.

He taught with enthusiasm and with great clearness of demonstration, urging his pupils to seize every opportunity for handling wet specimens, of making their own collection, and inviting them always to note the frequency in the size, shape, and extent of the paranasal cavities, as well as the occasional absence of one or more of them. During these years he was also accumulating the material for his classical work on diseases of the nose. His large publication on diseases of the larynx—which has been translated into English—was based on later work when he had left the Poliklinik for the Allgemeines Krankenhaus. Here he remained, teaching gradually dwindling classes during the post-war period. Hajek visited London when he delivered the Semon Lecture in 1928. He foresaw the clouds gathering for the second great war. Years ago he told the writer of this notice that Austria must inevitably fall into the clutches of either Germany or Russia. When the first of these catastrophes fell on Vienna, and the savage ill-treatment of the Jews started there, he appealed for help to this country. His fellow laryngologists and his old pupils here, as well as in Canada and America, enabled Hajek and his wife to reach London in 1938. The whole amount of money they were allowed to bring out of Austria was 10 marks each, and the only gold permitted was that of their wedding rings. He had to dispose of his gold watch before leaving Vienna. Among the few personal belongings he carefully brought over were some of his original anatomical specimens, which he gratefully presented to the Museum of the Royal College of Surgeons. The library there also accepted some original notes of his lectures made by a visitor to the Poliklinik in 1893. He arrived here broken in health, but his dwindling years were made as comfortable as circumstances would permit. He was most appreciative of his reception and of his welcome in the Section of Laryngology of the Royal Society of Medicine, of which he was one of the few Honorary Members. It was touching to hear how cheered he was simply by the sense of freedom and liberty in this country, explaining that this was daily shown by his being permitted to sit down on any seat, in any public park or garden, without being driven off by a member of the Gestapo.

Hajek was not commercially minded. His enthusiasm was for research, for writing, and particularly for attracting and teaching students. This teaching was made welcome by his evident eagerness to demonstrate the importance of intimate knowledge of anatomy in the practice of our art. In his work, his writings, and the inspiration of his pupils he was what the French call "*un grand maître*." It is distressing to think that the last two professors in what used to be the most famous school of laryngology in the world were driven from Vienna to die in exile. We have some little comfort in recollecting that they found welcome shelter in the two great democracies.

SIC. T.

DAVID FORSYTH, M.D., D.Sc., F.R.C.P.

Consulting Physician to Charing Cross Hospital

We regret to announce that Dr. David Forsyth, for many years physician to Charing Cross Hospital and the Evelina Hospital for Children, died on April 10 at his home in Weymouth Street. He was a general physician who made a special study of childhood and whole-heartedly embraced the doctrine and technique of psycho-analysis.

David Forsyth, son of Alexander Forsyth, M.D., was born at Greenwich on November 24, 1877. He studied medicine at Guy's Hospital and won the Rogers prize of the University of London after graduating in medicine in 1902; he took the M.D. degree in the following year and the D.Sc. in 1908, and became a Fellow of the Royal College of Physicians of London in 1910. After serving as demonstrator of physiology at Guy's he was elected to the visiting staff at Charing Cross and later at the Evelina Hospital, and for many years worked in the out-patient department and wards of both institutions. As a teacher at Charing Cross Dr. Forsyth made friends with generations of students and won their affectionate regard. He was a past-president of the Section of Psychiatry of the Royal Society of Medicine, and after the last war served as senior physician to the Psychiatric Clinic of the Ministry of Pensions. He was a member of the Child Study Society, the British Psychological Society, and the International Psycho-Analytical Association. His earliest book was *Children in Health and Disease*, published in 1909; *The Technique of Psycho-Analysis* followed in 1922, and *Psychology and Religion* in 1935. Among his many papers on the mental aspects of health and disease may be mentioned those on

diagnosis of neurotic conditions in general practice published in the *British Medical Journal* and on the psychological effects of illness on children published in the *Lancet*, also contributions on psycho-analysis to the *British Journal of Psychology* and the *Psycho-Analytical Review*. He was the author of a paper on the care of children under school age in the *Journal of State Medicine*, a report to the Ministry of Health on the mental health of the child, and of sections on the medical inspection of children in the City of Westminster Health Society's annual reports 1912–16.

"M.B." writes:

It must have needed great courage, twenty-five years ago, for a physician in a teaching hospital publicly to declare himself favourable to Freud's doctrines. All medical circles would nowadays accept (with more or less graciousness) much that formerly provoked ridicule and contumely. Such prejudice Dr Forsyth was willing and able to bear, and consequently generations of students were enabled to diagnose and appreciate the "psychogenic" symptom many years ahead of accepted teaching. Forsyth's uncompromising advocacy of clear and progressive thinking inevitably led to some unpopular conclusions concerning not only medicine, but politics and religion also. While not insensitive to *public feeling, his battling with custom, prejudice, and disease* remained unmodified. Hospital work offered no scope for the psycho-analytic therapy in which he excelled, so that it is left, perhaps, even more to his patients than his colleagues to appreciate the fineness of his therapeutic gifts, his soundness of judgment, and his integrity. His loss will touch many people very deeply.

[The photograph reproduced is by Elliott and Fry, Ltd.]

A. STANLEY GRIFFITH, C.B.E., M.D.

We regret to announce the death on April 9 of Dr. A. Stanley Griffith, whose important scientific studies of tuberculosis earned him the Weber-Parkes prize and medal of the Royal College of Physicians in 1927. He had lived for many years past at Newnham Croft, Cambridge, working at the University Field Laboratories as a member of the scientific staff of the Medical Research Council.

Arthur Stanley Griffith was born in 1875 and graduated M.B., B.Ch. of the Victoria University, with honours, in 1897, whereupon he was awarded the Derby exhibition at the Liverpool School of Medicine. In 1901, after holding for two years the Alexander Fellowship in Pathology at the Thompson Yates laboratory in Liverpool, he proceeded M.D. and obtained the D.P.H. of the English Royal Colleges. Stanley Griffith's quality as a bacteriologist then found recognition and congenial employment for seven years (1903–10) as resident scientific investigator under the Royal Commission on Tuberculosis; when that task came to an end with publication of the Commission's final report he continued to work at his subject with a Grocers' research scholarship, and held this for three years until he joined the scientific staff of the Medical Research Committee, as it was then known. The University of Cambridge gave him the Ph.D. degree in 1926, and his services to medical sciences and public health were publicly acknowledged by the award of the C.B.E. Stanley Griffith was a member of the Pathological Society of Great Britain and had been a member of the British Medical Association for forty-one years.

Sir Arthur MacNalty writes:

In 1900 Koch startled the world by his announcement that bovine tuberculosis was comparatively harmless to man. The British Government set up a Royal Commission to investigate the subject. Their chief workers at the Commission's experimental farm were Arthur Eastwood, a distinguished pathologist, and two young brothers, A. Stanley and F. Griffith, whose investigations at the Liverpool School had already revealed their brilliance and skill as research bacteriologists. In 1909, when resident medical officer at Brompton Hospital, I supplied material for the Royal Commission's investigation. It was then that I made the acquaintance of A. Stanley Griffith and his brother, an acquaintance which soon ripened into friendship in the years of co-operative work which were to come. The work of the Royal Commission, recorded in its reports, proved the pathogenicity of bovine tubercle to man. Much of this conclusion was due to Stanley Griffith's admirable technique for isolating and identifying bovine strains of the tubercle bacillus, and all the workers enhanced their scientific reputations. The Royal Commission's work finished, Eastwood and F. Griffith accepted appointments in the Pathological Laboratories of the Local Government Board (afterwards the Ministry of Health), and Stanley Griffith continued his research work on tuberculosis as a whole-time worker for the Medical Research Council at the University of Cambridge Field Laboratories, Milton, near Cambridge. As organizer and secretary of the Tuberculosis Committees of the Medical Research Council, I found his help and advice of the greatest possible value in investigating the many problems which came before these Committees.

Stanley Griffith whole-heartedly devoted himself to typing the tubercle bacilli found in various forms of non-pulmonary tuberculosis. In 1937 he reviewed the position in *Tubercle* (August issue, pp. 529–43) and gave a comprehensive table showing the percentage of cases infected with the bovine type of bacillus, the result of some twenty-six years' intensive and meticulous work. Some years previously W. T. Munro had drawn my attention to his discovery of bovine types of the bacillus in cases of pulmonary tuberculosis in Scotland. Dr Munro and Griffith worked at this problem together, and in 1938 the latter (in a paper with Smith) showed that 9.1% of 342 pulmonary cases from rural and small urban districts in the north-east of Scotland and 4.4% of 294 pulmonary cases from the City of Aberdeen yielded tubercle bacilli of the bovine type (*Lancet*, 1938, **1**, 739). In addition to this laborious work Griffith worked with Prof. J. B. Buxton on B.C.G., and was the author of important reports to the Medical Research Council on this subject.

Stanley Griffith was a stern critic not only of other men's work but of his own. He had a high standard of scientific excellence in the light of which he worked. He "shunned delights and lived laborious days," often, one fears, at the expense of his own mental and physical powers. Tall and thin, with clear-cut intellectual features, he was modest and retiring and the kindest of men. His published papers, fundamental as they are, reveal but a tithe of the great knowledge he possessed of the bacteriology of tuberculosis. Of late years he had broken down in health, and the end when it came was a source of sorrow but no surprise to his friends.

Since writing this the sad news has come that F. Griffith and W. M. Scott, my former colleagues at the Ministry of Health, have been killed by enemy action. F. Griffith wrote to me a few days ago about his brother's patience during his long illness. The brothers were devoted to one another and in death they have not been divided.

DUDLEY M. STONE, M.R.C.S.

Senior Assistant Medical Officer, *X*-Ray Department, St. Bartholomew's Hospital

We regret to announce that Dr. Dudley Macaulay Stone, well known for his work in radiography, died on April 15, after a long illness.

He was born in London on March 3, 1881, the son of John H. Stone, M.A., F.L.S., and from Bedford School entered St. Bartholomew's Hospital, where he became very popular and distinguished himself at football and other sports. He was also an expert yachtsman, and his skill in photography went far beyond that of an amateur. After qualifying M.R.C.S., L.R.C.P. he worked as house-surgeon at the Metropolitan Hospital and then began to specialize in radiology, becoming medical officer in charge of the *x*-ray department of the City of London Hospital for Diseases of the Chest and radiologist to St. Paul's Hospital. Throughout the last war he served in France, with a number of Bart's friends, at Le Touquet, where he had charge of the *x*-ray and electrotherapeutic departments of No. 1 British Red Cross Hospital. His mastery of the technique of photography had been recognized by Dr. Lewis Jones and Dr. Hugh Walsham while he was a student, and on returning to civil life after the war he rejoined

the *x*-ray department at St. Bartholomew's as chief assistant. In private practice in Harley Street, Dudley Stone gave valued help to the patients of many colleagues, medical, surgical, and dental. Among his few published papers was one on a method of preventing dust from getting between the fluorescent screen and the lead glass, written for the *Archives of Radiology and Electro-Therapy*.

K. M. W. writes:

Dudley Macaulay Stone's death at the age of 60 removes from St. Bartholomew's Hospital a familiar figure. For forty-two years "Dobbs" has been seen there, ever since he entered King Henry the Eighth's gateway as a student of 18 fresh from Bedford Grammar School. Only during the four years of the last war was he absent from Bart's, when he was serving as radiologist to the Duchess of Westminster's Hospital at Le Touquet. Indeed, Dobbs was very rarely absent from duty. If he had not adopted a medical career he would have found a congenial career in the Navy. He had that devotion to duty, that thoroughness in the discharge of anything he had undertaken, which are characteristic of most sea-going men. And the sea had a strong fascination for him. He sailed his yacht with the same mastery with which he manipulated his *x*-ray plant. No slipshod methods were tolerated on board, as the writer, who once undertook the washing-up of plates in the forecastle, can well testify. High standards were set by the skipper and expected also of the crew. (The plates were rewashed.)

Stone could have made a success of several careers, among others as a business man. But there is no doubt that he selected the right one. Keenly interested in all forms of apparatus and a first-class amateur photographer, the growing *x*-ray department of the hospital claimed him as naturally as a pond claims a duckling. He neither attempted nor achieved any high medical distinction, for practice was of more importance to him than theory. And what an immense amount of work he got through without any fuss or bother! Nobody ever saw him ruffled, nor did the humorous glint ever depart from his eye. An extra barium meal on a morning that was already overcrowded was, after all, only a trifle. It had to be done and it *was* done. He will be more difficult to replace than many a man with glittering academic distinctions.

And he will be missed in other circles than that of St. Bartholomew's, for he was a man of many hobbies. Yachtsmen, philatelists, and business men alike will feel that a "character" has disappeared from among them. Stories will be retold, reminiscences of old Stone exchanged, memories of good times together revived. Good-bye, Dobbs. You would never have liked the usual platitudes in your obituary notice. You liked the plain unvarnished truth.

J. GRAHAM FORBES, M.D., F.R.C.P.

We regret to announce the death on April 8 of Dr. J. Graham Forbes, late Senior Medical Officer in the Public Health Department, L.C.C. James Graham Forbes was educated at Cambridge and St. Bartholomew's Hospital, qualifying M.B., B.Ch. in 1898; he proceeded to the M.D. in 1901, taking his D.P.H. in the same year. In 1904 he took the M.R.C.P., and was elected to the Fellowship in 1920. Dr. Forbes was house-physician and assistant demonstrator in pathology at St. Bartholomew's, and clinical pathologist and bacteriologist to the Hospital for Sick Children, Great Ormond Street. Among his publications was the well-known *Diphtheria, Past and Present: its Aetiology, Distribution, and Prevention*, published in 1932. We are indebted to a former colleague for the following appreciation:

The outstanding features of Forbes's character which were conspicuous in later life were those of individualism and drive, and these often made him a determined critic. These characteristics he no doubt owed to the fact that he was the son of a well-known high churchman and received his early education at Clifton. Although not of his year, I remember him as a medical student at Cambridge, where he belonged to a particular clique of students. Association, however, was more intimate in the dissecting room and in the histological laboratory, and here one was able to see the beginning of those characteristics which were so prominent in later life. I lost contact with him when he became a student at St. Bartholomew's Hospital, and association did not come again until he was pathologist at the Children's Hospital at Great Ormond Street. There is no doubt, however, that he continued his successful career at St. Bartholomew's. He held appointments there both of house-physician and of assistant demonstrator of pathology, and afterwards held various outside appointments such as surgeon to the Royal Blue Regiment, medical officer to the Anglo-French Boundary Commission, where he no doubt learned much of tropical diseases, and later again as assistant physician to the London Royal Chest Hospital. Physically Forbes never was strong, and it is surprising what an amount of energy and vigour he threw into his life's work in spite of poor health, which kept him away from duty for at least two long periods. Pathology and work in a laboratory were undoubtedly the types of work for which his mind was developed, and this is shown by the good work he did for the Children's Hospital, where he acted as their pathologist. One of his most valuable contributions as pathologist was his report on the prevalence of the gonococcus in the genitals of apparently healthy children admitted to the wards. It is a great pity that this report was never made public, for it would have saved the reputation of many doctors working in hospital and would have silenced the always too ready criticisms of lay members of hospitals, who obviously do not know anything of medicine and yet in their ignorance are only too ready to criticize and condemn the medical profession for ineptitude.

Most unwisely some of Dr. Forbes's friends advised him to give up pathology and become a school doctor under the L.C.C., for he had no interest whatever in administrative work, and the years he devoted to this task were no doubt wasted. In due time, however, an opportunity arose to transfer him to the County's Pathological Laboratory at County Hall, where he assisted the Principal Assistant Medical Officer in controlling infectious diseases in schools and carrying out the laboratory diagnostic work. It was here that he came into contact with the diphtheria control in schools. He very soon saw that diphtheria outbreaks in schools could not be controlled either by swabbing of contacts or by seclusion of carriers, and that the only remedy was universal artificial immunization of all susceptibles. From then on he made it his duty to preach this doctrine on every available occasion. Diphtheria control was the subject of his Milroy Lecture in 1929, and he made the amplification of this lecture his life's work, first in a publication by the Medical Research Council and finally in the publication of his monumental work on diphtheria, which to-day still holds the record.

Dr. Forbes retired from the Council service on attaining the retiring age in 1938, and his friends are happy to think that he was able to enjoy some three years of quiet and leisured life. To his friends he will always be remembered as a vigorous and outspoken critic on subjects of which he had made a deep and toilsome study.

EDMUND BARKER, L.R.C.P. & S.Ed., L.R.F.P.S.G.

For many years one of the best-known medical figures throughout the East Riding of Yorkshire, Dr. Edmund Barker died suddenly in his chair on April 10, having just finished his morning surgery.

A Yorkshireman in the truest sense, Dr. Barker was born at Hovingham 71 years ago and, although his father was a farmer, he came of a medical family, for his grandfather, Dr. Thomas H. Barker, was a noted surgeon of York. Before qualifying in Glasgow in 1895 he had been a medical student at Belfast and Leeds. He had previously served as a medical apprentice at Doncaster Infirmary and was for some time an unqualified assistant in general practice. When, therefore, he started practice in the Hessle Road district of Hull over forty years ago he was a man of very wide experience. His geniality and kindly interest in everything and everybody in his district gave him an amazing knowledge of the community among whose members he spent so long a period. Edmund Barker had an unsurpassed knowledge of the Yorkshire dialect, and his amusing tales of his experiences in practice will long be remembered by many of his colleagues.

For many years he took a very active interest in all things med[illegible] in the city. He was an original member of the Hull Insurance Committee and Local Medical and Panel Committee, of which he was chairman for some years. He was a past-president of the Hull Medical Society, and was a keen member of the British Medical Association until increasing difficulty in getting about compelled him to give up active participation in local medical affairs. He possessed a wonderful memory and was an exceedingly clear thinker; his advice was, therefore, frequently sought by his colleagues on difficulties in practice of all kinds. A unique tribute to his great popularity with his fellow practitioners was paid to him when he retired from committee work, for he was entertained to dinner and presented with a piece of plate to commemorate the occasion. He is survived by his second wife and his only daughter, who is the wife of Dr. Stanley Worthington of the Ministry of Health Regional Medical Service.

Edmund Barker, writes "J. N.," was known as one of the oldest doctors still in active practice in Hull. And in his practice he always was active and energetic. He took considerable interest in medical politics, from the time when he was a participator in "the battle of the clubs" when in practice in Northumberland down to the early stormy days of the National Health Insurance Act. When panel practice was an accomplished fact he became a member of the Hull Panel and Local Committee. He also served on the local Insurance Committee up to his retirement from all committees a few years ago. He was a good committeeman, though not a particularly good speaker. His own way of putting it was that he was all right sitting at a table and talking: but that when he had to stand up he was too nervous to be any good. Barker was versatile in his tastes and temperament. He exhibited many of the best characteristics of the good Yorkshireman that he was. In business matters keen and a good bargainer; in his personal and social side hospitable, generous, and ever ready to help lame dogs over stiles. He loved the company of friends, and being a good raconteur, with a great fund not merely of tales and stories but of general knowledge, his friends found in him a good companion. He was largely a follower of Belloc and Chesterton; and loved the old-fashioned country inn far above any of the modern monstrosities with plush and chromium decorations, and was a genuine authority on the old inns of the North of England. He had many tastes, interests, hobbies. A good botanist, he had specialized to a considerable extent in the study of ferns. Like many brought up in the country, he knew much about bird life, not so much from the scientific point of view as from the aesthetic side. He was a good fisherman; and when he practised in Northumberland was a member of the Conservancy Board, on which he did good work for the preservation of piscine life and the care of trout and other streams. In fact, he was interested in almost every aspect of country and outdoor life: and for anyone who had similar tastes he was a delightful and instructive companion. In the more quiet aspects of life he had also many interests. He had been an ardent philatelist. He was well and widely read, his knowledge of the literature of Yorkshire especially being extensive; while he was devoted to certain types of Irish literature, and books dealing with that country—which he loved best after his own native Yorkshire. Barker was a stout believer in the traditions of his profession: and was never known to act in any unprofessional way towards a colleague. He was very human, alike in his faults and his virtues; always optimistic, and in his dealings with his fellows ever ready to believe the best and see the best side of anyone, until or unless experience undeceived him. He was a staunch friend, and in that capacity he will be sorely missed by one who had been admitted to his close friendship to such a degree that we two came to be described as "stable companions."

G. W. C. KAYE, D.Sc., F.R.S.

The death of Dr. George William Clarkson Kaye, F.R.S., on April 16 at the age of 61 removes a distinguished physicist who had many and important contacts with medical science, and through it with medical practice. Dr. Kaye had been superintendent of the physics department of the National Physical Laboratory, Teddington, for nearly twenty years. Among the many high offices held by him were those of president of the Roentgen Society and of the British Institute of Radiology, secretary of the International X-ray and Radium Protection Committee, member of the National Radium Commission and its secretary for four years, member of the Grand Council of the British Empire Cancer Campaign, chairman of the Noise Investigation Committee appointed by the Minister of Transport, and honorary editor of the *British Journal of Radiology* for thirteen years. He had also been Mackenzie Davidson lecturer and medallist and Stanley Melville memorial lecturer and medallist, and thus commemorated two pioneers in medical radiology.

ERIC SNELL, M.A., M.B.

The medical profession in Nottingham has sustained a great loss by the death of Dr. Eric Snell, which took place on April 6 after a long illness patiently borne.

James Eric Boobbyer Snell, who was 63 years of age, came of a medical family of the East Midlands. He was himself the son of a doctor, Dr. Enoch Snell, and two of his brothers are members of the medical profession—Dr. Montague Snell of Nottingham, and Dr. Rupert Snell of Wimbledon. One of his two sons, Surgeon Lieut. Thomas Brooking Snell, R.N.V.R., has kept up the medical tradition of the family; his other son is a flying officer in the R.A.F.

The late Dr. Snell was associated with Nottingham during the whole of his life. He was educated at the High School there, afterwards going on to Caius College, Cambridge. In 1898 he took the Natural Sciences Tripos with honours, and continued his medical education in London at St. Thomas's Hospital. He qualified in 1902 and settled down in practice in his own Nottingham, where he quickly gained wide esteem as a family practitioner among both his patients and his medical colleagues. The large and representative assembly which filled the church at Edwalton, the village where he had lived in recent years, on the occasion of his funeral was a testimony to the regard in which he was held.

Dr. Snell had been a member of the British Medical Association for thirty-seven years. When the Association held its Annual Meeting in Nottingham in 1926 he was co-editor with Dr. Galloway of the admirable *Book of Nottingham* prepared for the occasion. He was an active member of the Nottingham Medico-Chirurgical Society, and was identified in various ways with University College and with the branch of the British Red Cross Society. His three daughters are serving in a Red Cross hospital. His illness began in a severe form in the autumn of 1939. He knew that it could have only one end, but his attitude was one of such oustanding courage as to cheer and inspire all who came in contact with him in recent months. He married the daughter of the late Sir Thomas Shipstone, a well-known Nottingham philanthropist closely associated with the Nottingham General Hospital, who survives him.

RUBY BLACKLOCK THOMSON, M.B., Ch.B., D.P.H.

Dr. Ruby Thomson was born in May, 1889, at Hong Kong, the elder daughter of Dr. J. C. Thomson, a member of the Government Medical Service of that Colony. She came to England at the age of ten, and in 1912 graduated in medicine at Edinburgh University, and in 1923 took the D.P.H. (Ed. and Glasg.). She held appointments at Toxteth Infirmary, Liverpool, at Victoria Hospital for Sick Children, Hull, and under the County Council of Staffordshire, and during the last war was resident medical officer at Woolwich Arsenal. In 1919 she served for some months under Dr. George Buchan at Willesden, and in July of that year was appointed medical officer in charge of maternity and child welfare to the Metropolitan Borough of Fulham. This post she held till last June, when she retired on account of ill-health. She had been a member of the B.M.A. for twenty-eight years.

Dr. Thomson writes A. H. N.) was known to suffer from high blood pressure. During the evening of April 2, while chatting with friends, she suddenly complained of giddiness, slid from her chair unconscious, and by shortly after midnight had slipped out

of life, leaving an appreciable gap in the senior ranks of the Public Health Service and a wider one in the hearts of her many friends. On the intellectual side Dr. Thomson inherited an excellent brain of the accurate order and always had a complete grasp of the administrative and clinical details of her work. She did not "think," she knew, and one could go to her, as indeed many did, in the confidence that information would be most willingly given and would be correct. The same applied to matters of general knowledge, in which her interests were wide. In the Borough of Fulham she set and maintained a high standard of work and had the full respect and confidence of councillors, officials, and public. At medical meetings she did not often speak, but when she did it was to the point. It was, however, in her personal relationships that Dr. Thomson made her greatest impression. She had character and personality in an unusual degree. With the highest code of personal and professional conduct that never condoned slackness or inefficiency in herself or in others, a shrewd and realistic judgment of persons and motives, and a directness of speech which in others might have given offence, she combined much social tact and a generous, enthusiastic, and lovable nature that won friends and willing service wherever she went and among all sorts of people, not least among the poor mothers of Fulham.

It was with a great sense of shock and grief (writes J. A. S.) that the many friends of Dr. Ruby Thomson heard of her sudden death. Dr. Thomson worked in Fulham from the earliest days of maternity and child welfare activity in the borough, and took her full share in the inauguration of the Council's first maternity home, infant welfare clinics, day nursery, and babies' hospital. Her single-minded devotion to her work and her untiring efforts for the welfare of the mothers and babies in Fulham will long be remembered both by her colleagues and her patients, for whom she had a high sense of responsibility and whose personal troubles she so often shared. Dr. Thomson was for many years the Council's representative on the National Baby Week Council and the Association of Maternity and Child Welfare Centres. Her activities in these spheres brought her a wide circle of friends and acquaintances. Her loss will be widely felt, for her honesty of purpose and enthusiastic interest in every phase of maternity and child welfare work endeared her to all.

Universities and Colleges

UNIVERSITY OF GLASGOW

A graduation ceremony was held on April 19, when the following medical degrees were conferred:

M.D.—*Margaret D. Crawford, *A. C. Lendrum, †R. S. Barclay, ‡D. C. Dewar, ‡A. Hutchison, ‡J. S. McGregor, ‡J. McIntosh, ‡ §I. M. Scott, §J. C. Hogarth, §J. E. McClemont, D. A. McCracken, §J. L. Rennie, §A. M. Spence.

M.B., CH.B.—‡R. L. T. Hill, J. Alexander, A. Bancewicz, W. G. Barrie, P. Barron, A. S. Biggart, J. D. Blair, Agnes M. Brogan, J. T. S. Brown, May M. Brown, R. J. Cairns, W. Chambers, Christina C. Christie, W. McC. Crawford, D. C. Devine, W. D. W. Dick, A. B. Donald, J. McD. Glennie, A. Gordon, W. McL. Gregor, H. R. C. Hay, A. L. Henderson, H. D. Hewitt, Catherine T. Howat, A. S. Hunter, Frances M. J. Hutchinson, A. Jamieson, Mary C. Kilpatrick, Dorothy A. Knox, J. D. Laurie, M. B. Leitch, J. Lockie, T. McCarroll, I. R. McCaul, R. O. O. McCrone, H. M. Macfie, J. Mackechnie, S. Y. MacKechnie, A. MacLachlan, L. G. MacLachlan, A. McLaren, Christina R. C. MacLean, N. McLean, Pearl A. I. MacLeod, I. F. MacMath, A. H. Miller, A. G. B. Miller, D. G. Munro, A. A. Murray, A. F. Nelson, J. A. Ogilvy, W. Rankin, F. C. Rodger, T. Sergeant, M. Shafar, A. H. Smith, S. Soldberg, W. Steele, J. S. Stevenson, W. J. B. Templeton, Eleanor Tennant, Janet Waugh, J. B. de V. Weir, G. D. Wilson, D. Wright.

The following prizes, among others, were awarded:

University Prizes.—Bellahouston Medals: Theodore Crawford, A. S. Rogen, A. T. M. Wilson. Captain H. S. Ranken, V.C., Memorial Prize: D. Jamieson.

Special Class Prize.—Surgery, Macleod Medal: R. A. P. Brown.

* With honours. † With high commendation.
‡ With commendation. § *In absentia.*

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a quarterly meeting of the Council of the Royal College of Surgeons of England, held on April 17, with the President, Sir Hugh Lett, in the chair, the Walker Prize for Cancer Research was awarded to Dr. Peyton Rous of the Rockefeller Institute, New York, for his discovery and systematic investigation of filterable tumours.

It was decided to use the bequest from the late Sir Charles Tomes as an endowment for a lectureship on some subject connected with odontology.

Mr. H. S. Souttar was re-elected a member of the Court of Examiners for the ensuing year.

Mrs. Antoinette Pirie, Ph.D., was appointed a Leverhulme Scholar to work in the laboratories of the Imperial Cancer Research Fund on "The Effect of the Spreading Factor on the Reaction between Tumour Viruses and the Cells which they Infect and in which they Multiply."

The Cartwright Prize for 1936-40 was not awarded. The subject for essays for the years 1941-5 is "The Replacement of Lost Tissues following Injuries of the Jaws."

Mr. J. W. Walker and Mr. T. H. Butler, being members of the College of over twenty years' standing, were elected Fellows of the College.

A letter was received from the Imperial Cancer Research Fund expressing appreciation of the award by the College of two lectureships annually to members of the scientific staff of the Fund.

It was decided that in the forthcoming Primary and Final Examinations for the Fellowship the papers may be written alternatively in Manchester or London and the viva voce will be in London only. There will be no Final Examination for the Fellowship in February, 1942.

Diplomas

Diplomas of Membership were granted to G. C. Purslow and J. R. J. Winter.

Diplomas in Child Health were granted, jointly with the Royal College of Physicians of London, to the following candidates:

C. L. Davidson, Mary G. Tate, Brenda M. Jones, H. W. Bradford, Beryl E. Barsby, J. J. Linehan, G. P. McLaughlan, Margaret E. M. McLaughlin, F. C. Oliphant.

CONJOINT BOARD IN SCOTLAND

The following candidates, having passed the final examinations, have been admitted L.R.C.P.Ed., L.R.C.S.Ed., L.R.F.P. and S.Glasg.:

A. Abrahams, Marguerite S. Annett, J. Bhageerutty, J. W. Bringan, L. G. Christopher, H. O. Engel, A. W. Paterson, E. C. Richardson, H. Sandler, B. Schaefer, J. M. Sherriff, A. Shields, R. J. G. Sinclair, W. J. Y. Speedy, W. F. Vancrosson, J. H. Wakely, W. Waterston, O. M. Watt, G. A. Y. West, J. P. Weiss, V. G. Whelan, J. M. Yablonowitz.

The following graduates of recognized foreign universities were also admitted Licentiates:

S. Frank, Margarete J. Hildebrand, T. Horowitz, Liselotte Lennhoff, Kate Maunsell, O. Olbrich, E. R. Schuster.

Medical News

The Harveian Lecture for 1941 on "The Coroner, the Doctor, and the Public" will be delivered by Dr. John Taylor, at 26, Portland Place, W., on Monday, May 5, at 2.30 p.m.

The Dr. Mann Lectures for 1940-1 on "Chemotherapy" will be delivered before the Royal Society of Arts (John Adam Street, Adelphi, W.C.) by Dr. G. Stafford Whitby, director of the Chemical Research Laboratory, Teddington, on Mondays, April 28 and May 5, at 2.30 p.m.

The special afternoon lectures to be given this spring at the Royal Institution, 21, Albemarle Street, W.1, include one on Tuesday, May 20, by Sir Joseph Barcroft, F.R.S., on the "Development of Function in the Mammalian Organism," and another, on May 27, by Dr. C. F. A. Pantin, F.R.S., on "The Origin of Life"; both at 5.15 p.m.

Major-General Sir John Kennedy, vice-chairman of the Executive Committee of the British Red Cross and St. John War Organization, will read a paper on "The Red Cross in War" before the Royal Society of Arts (John Adam Street, Adelphi, W.C.) on Wednesday, May 7, at 2.30 p.m.

A general meeting of the Medical Society for the Study of Venereal Diseases will be held at 11, Chandos Street, W., on Tuesday, April 29, at 2.30 p.m., when there will be a discussion on "How to Get the Infected Woman under Treatment," to be opened by Dr. Morna Rawlins.

Important discussions in London on questions relating to prisoners of war, including that of getting food to them, have taken place between the British Red Cross and St John War Organization and two delegates of the International Red Cross now on their way back to Geneva. Mlle. Lucie Odier, member of the International Committee of the Red Cross, and Dr. Marcel Junod, the chief delegate, who has seen British prisoners of war and interned civilians in Germany and Occupied France, have established an even closer contact with all Red Cross and St. John Departments and have cleared up a number of matters regarding prisoners of war and internees in enemy hands.

We have received the first number of a new American medical periodical entitled the *Journal of Clinical Endocrinology*, which is to be issued monthly at an annual subscription rate of $6.50. It is published under the auspices of the Association for the Study of Internal Secretions, and is intended to be complementary to the association's older journal, *Endocrinology*, which was first published in 1937.

Dr. Mazyck P. Ravenel, editor-in-chief of the *American Journal of Public Health*, has been made editor emeritus, and is succeeded by Dr. Harry Stoll Mustard, director of the De Lamar Institute of Public Health of Columbia University, New York.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

During the week under review the incidence of whooping-cough has increased and that of measles decreased. The number of notifications for the other common infectious diseases has not been materially altered. Cerebrospinal fever continues to decline: the provisional figures for the two weeks ending April 5 and 12 are 335 and 282 respectively.

Whooping-cough

The further rise in the number of cases reported during the week has been due mainly to the increase in the notifications from London and the Home Counties. Of the three counties which showed the largest increase last week, Lancaster and Leicestershire recorded a fall of 39 and 12 cases respectively, whilst Yorkshire, West Riding, had a further increase, 20 more than in the previous week. The principal increases in this county were from Huddersfield C.B. 20, and Batley M.B. 18.

Measles

Although the incidence of measles decreased for the country as a whole, London and the surrounding counties had an increased number of cases on the previous week. The increases were Bedfordshire 5, Berkshire 35, Hertfordshire 63, Kent 47, London 21, Middlesex 214. The large rise in Middlesex was due to the increased incidence in Edmonton M.B., where the cases rose from 109 to 215, and Enfield U.D. with a rise from 59 to 189.

Dysentery

The total number of cases showed an increase of 12 on the total for the previous week. The most notable of the localized outbreaks are Kent, Dartford R.D. 9; Leicestershire, Leicester C.B. 19; Glamorganshire, Cardiff R.D. 21. No cases were reported from these areas in the preceding week.

Paratyphoid Fever

Ninety-one cases of paratyphoid have been reported from Scotland during the week under review, making a total of 173 for the last two weeks. The counties of Angus 13, Inverness 48, Moray and Nairn 15, and Ross and Cromarty 87, account for practically all the cases during these two weeks.

Scabies

From several areas in England and Scotland reports have shown an increase in the incidence of scabies: the spread of this disease has caused concern to local authorities. Cases of scabies have been increasing during recent years and have proved intractable. The fact that it is not notifiable and that local health departments have no statutory powers for dealing with it makes the condition extremely difficult to control.

No. 13

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended March 29, 1941.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

E.M.S. PAYMENT FOR SECOND OPINION OR SPECIAL INVESTIGATION IN SERVICE CASES

The Ministry of Health asks that Circular 2326, which is printed below, be substituted for that bearing the same number which was issued on April 2 and summarized in these columns on April 12 (p. 44).

"I am directed by the Minister of Health to refer to paragraph 3 (e) of Circular 2176, in which it is stated that where, in respect of Service casualties or sick referred to out-patient departments for the purpose, a second opinion or special investigation (or both), including, if required, a report in writing, is necessary, a payment of £1 1s. may be made by the hospital to the practitioner conducting the examination. It appears from inquiries which the Minister has received that there is doubt as to the type of case in which a guinea payment should be made. Subject to any revision of the terms of the circular that may be announced, the following conditions must be satisfied in order to bring a case within paragraph 3 (e):

1. A request for a second opinion clearly implies that a first opinion on the patient's medical condition (and not merely a statement of his symptoms) must be furnished by the medical officer of his unit or of the hospital referring him. Normally this should be in writing and accompanied by a written statement of the matters on which a second opinion or investigation is required.

2. Normally the patient must have been seen by a physician or surgeon at the hospital to which he is referred. Where, however, it is the custom of the hospital to allow patients to be referred at the request of an outside medical officer direct to a special department, the report and opinion from that department may be regarded as a 'second opinion,' subject to the condition set out in the preceding paragraph.

3. A second opinion, which would normally be in writing, reporting on the patient's condition (or reporting the results of the investigation) must have been returned to the referring medical officer.

4. In no case is more than one guinea payable in respect of a particular patient, even if it is necessary for him to see several members of the hospital staff or to attend on a number of occasions for the purpose of the required second opinion or special investigation.

When hospitals claim reimbursement of guinea payments on Form A.G.136 they will be required to certify that the four conditions set out above applied in every case. Where no such certificate can be given, as, for example, in the case of patients who are merely referred, with a statement of their symptoms, for such treatment as the hospital staff think proper, guinea payments cannot be reimbursed by the Department."

Medical Services of H.M. Forces Appointments

ROYAL NAVY

Surgeon Lieut. B. R. Alderson to be Surgeon Lieutenant-Commander.

Surgeon Lieut. E. James (Emergency) to be Surgeon Lieutenant-Commander (Emergency).

Surgeon Lieut. L. Merrill has been transferred to the Permanent List with original seniority of April 3, 1936.

ROYAL NAVAL VOLUNTEER RESERVE

Probationary Surgeon Lieut. N. M. Hancox to be Surgeon Lieutenant.

To be Temporary Surgeon Lieutenants: M. W. Bird, R. Browning, N. F. E. Burrows, J. A. Bowen-Jones, P. J. Byrne, A. D. Bell, E. R. Bowes, E. A. Bisson, J. Barr, R. A. Andrews, T. T. Baird, H. M. Balfour, J. A. O'Callaghan.

Probationary Temporary Surgeon Lieuts. R. E. D. Wheeler, R. C. S. Benson, M. J. Clow, G. K. Burton, N. A. C. Best, J. C. Ballantyne, F. R. Badenoch, D. R. Barry, T. E. Barwell, P. A. Bennett, J. L. Adlington, R. G. Allen, J. K. Armstrong, J. M. Berry, J. G. Brown, J. I. Cunningham, I. Chadderton, J. B. Longmore, P. C. Collinson, B. D. Stutter, D. M. F. Carter, C. H. Bartlett, P. A. Byrne, W. J. Drummond, M. W. Fletcher, H St C. C. Addis, R. G. Thomas, E. M. B. Clements, D. A. Jennings, G H Swapp, J. C. G. Abraham, F. C. Barlow, T. A. Best, G. N. Arthurs, G. B. Locke, A. J. Barrett, A. Ackroyd, R. G. S. Whitfield, C C. Kirby, W. J. Matheson, G. H. T. Williams, H D. McGorry, A E Sherwell, R. B. Mayfield, I. Miskelly, H. S. Provis, J. H. Garnett, A. H. Zair, R. S. P. Hawkins, M. McC. Weir, D. M. Morrisey, P. C. Lawson, D N Leeming, F. A. Henley, N. J. de V. Mather, C. B. Holland, J. H. Foxton, W. O. Thomas, N. S. Lockyer, D. H. Johnston, G. C. Haywood, W. B Jamieson, J. W. Wood, G. S. Wigley, J. F. Ramsden, C. J. Milligan, J D Manning, T. D. C. Ritchie, C. G. Campbell, R. P. Crick, J. McD. Christie, P R K. Coe, D. Craig, and H. H. Crabb to be Temporary Surgeon Lieutenants.

ARMY

Lieut.-Colonel (temporary Colonel) D. C. Monro, K.H.S., from R.A.M.C., to be Colonel.

Colonel A C. H. Gray, O.B.E., retired pay, late R.A.M.C., has reverted to the rank of Major whilst employed during the present emergency.

ROYAL ARMY MEDICAL CORPS

Major and Brevet Lieut.-Colonel (temporary Lieut.-Colonel) A. E. Richmond, O B E., to be Lieutenant-Colonel.

Lieut.-Colonels A. N. Dickson, M.C., retired, I.M.S., and M. R. C. McWatters, retired, I.M.S., have reverted to the rank of Major whilst employed during the present emergency.

Captains (temporary Majors) F K Bush and E. S. Tweedy to be Majors.

Captain W. L. O'Donnell has relinquished his short-service commission on account of ill-health.

Short Service Commission. Lieut. (on probation) J. E. Miller has been confirmed in his rank.

REGULAR ARMY RESERVE OF OFFICERS

Colonel A. E. S. Irvine, D.S.O., late R.A.M.C., having attained the age limit of liability to recall, has ceased to belong to the Reserve of Officers.

ROYAL ARMY MEDICAL CORPS

Lieut.-Colonel I. R. Hudlestone, D.S.O., has ceased to belong to the Reserve of Officers on account of ill-health.

Captain C. W. Simpson has ceased to belong to the Reserve of Officers on account of ill-health.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

War Substantive Captain R. Dormer has relinquished his commission on account of ill-health.

ROYAL AIR FORCE

Air Marshal Sir A. V. J. Richardson, K.B.E., C.B., K.H.S., has been placed on the retired list at his own request.

Postgraduate News

A series of special lectures has been arranged under the auspices of the Honyman Gillespie Trust to be held in the West Medical Theatre, Edinburgh Royal Infirmary, on Thursdays, at 4.30 p.m., from May 8 to June 12, both dates inclusive. The lectures are open to all graduates and senior students, and details will be published in the postgraduate diary column of the *Supplement* week by week.

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W.—*Daily*, 10 a.m. to 4 p.m., Medical Clinics, Surgical Clinics and Operations, Obstetrical and Gynaecological Clinics and Operations. *Daily*, 1.30 p.m., Post-mortem demonstrations. *Tues.*, 11 a.m., Paediatric Clinic, Dr. R. Lightwood. *Wed.*, 11.30 a.m., Clinico-pathological Conference (Medical). *Thurs.*, 2 p.m., Dermatological Clinic, Dr. R. T. Brain; 2 p.m., Radiological Demonstration, Dr. Duncan White. *Fri.*, 12 noon, Clinico-pathological Conference (Surgical); 2 p.m., Clinico-pathological Conference (Gynaecological); 3 p.m., Sterility Clinic, Mr. V. B. Green-Armytage.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Section of Odontology.—Mon., 2.30 p.m. Paper by Mr. Edgar B. Manley: Experimental Investigation into the Early Effects of Various Filling Materials on the Human Pulp. Film by Mrs. Shirley Hughes: Development of Rodent Teeth.

Section of Psychiatry.—Tues., 4.30 p.m. Discussion: The Possibility of predicting Breakdown under Service Conditions. Openers, Surgeon Captain Desmond Curran, R.N.V.R., Wing Commander R. D. Gillespie, R.A.F., Colonel J. R. Rees, A.M.S., and Dr. Eliot Slater.

Sections of Otology and Laryngology.—Fri. Combined annual general meeting. Election of officers and council for 1941-2. 10.30 a.m., Discussion: Chemotherapy, Serotherapy, and Haemotherapy in Otology and Laryngology. Openers, Col. L. E. H. Whitby, Dr. H. F. Brewer, Mr. J. Angell James, and Mr. N. Jory. Short paper by Sir Milsom Rees: The Role of the Labyrinth in Man and Animals. A clinical meeting will be held in the afternoon.

Section of Anaesthetics.—Fri., 2.30 p.m. Annual general meeting. Election of officers and council for 1941-2. Short papers by Dr. K. C. McCarthy (Toledo, U.S.A.), Dr. E. A. G. Goldie, Dr. Francis Evans, and Dr. F. B. Mallinson.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos Street, W.—*Tues.*, 2.30 p.m. General meeting. Discussion: How to get the Infected Woman under Treatment. To be opened by Dr. Morna Rawlins.

ROYAL SOCIETY OF ARTS, John Adam Street, Adelphi, W.C.—*Mon.*, 2.30 p.m. Dr. Mann Lecture by Dr. G. Stafford Whitby: Chemotherapy. *Wed.*, 2.30 p.m. Dr. O. R. Tisdall: The General Practitioner and Scientific Thought.

SHAFTESBURY MILITARY HOSPITAL MEDICAL SOCIETY.—*Tues.*, 3 p.m. Prof. J. A. Nixon: The Treatment of Serious Gas Casualties.

Diary of B.M.A. Central Meetings

MAY

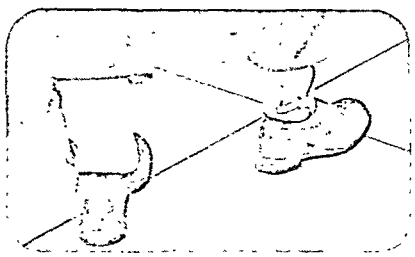
1 Thurs. Journal Board, 2.15 p.m.

B.M.A.: Branch and Division Meetings to be Held

WILTSHIRE BRANCH: SWINDON DIVISION.—At Victoria Hospital, Swindon, Wednesday, April 30, 8.30 p.m. Meeting. Address by Dr. I. G. Davies (Bristol).

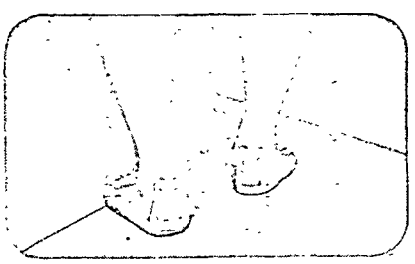
BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than the first post Tuesday morning to ensure insertion in the current issue.



BIRTHS

ACTON.—On April 9, 1941, at Exeter, to Muriel (*née* Gent), wife of Dr. Hugh Acton, of Okehampton, Devon, a son (David John).



LAMMING.—At the Jane Crookall Maternity Home, Douglas, I.O.M., on April 13, 1941, to Dr. Olive Mary Lamming (*née* Callow) and Captain Robert L. Lamming, F.R.C.S., R.A.M.C., a daughter.

DEATH

WOODMAN.—On April 15, 1941, suddenly, at Jersey, Carmen Sylva Road, Llandudno, (late of Baghdad) Gordon Stewart Woodman, F.R.C.S., beloved husband of Kathleen Woodman.

'Elastoplast' Dressings applied to the heel and other tender parts of the foot prevent blisters.

'Elastoplast' Dressings will not ruck up or become displaced in wear.

Increased incidence of minor wounds

The incapacitation often resulting from sore heels and toes can be averted by the application of an 'Elastoplast' Dressing. 'Elastoplast' Wound Dressings comprise an antiseptic pad of gauze medicated with Bismuth Subgallate on the elastic adhesive 'Elastoplast' base.

For N.H.I. prescriptions, these dressings, medicated with boric acid, are available in the four specified sizes.

The 'Elastoplast' Doctor's set contains 106 'Elastoplast' Dressings in various sizes, and is available through your usual surgical supplier at 8/6d.

THE FOOD PROBLEM

When the choice of food is limited, the relative value of different foods assumes considerable importance.

The intake of vitamins and mineral salts must be adequate and the diet properly balanced in order to attain a high standard of physical fitness.

Marmite supplies all the B vitamins and is in great demand for this very reason.

ERGOMETRINE
(B. W. & Co.)

The crystalline alkaloid used in Burroughs Wellcome & Co. ergometrine preparations is of the highest degree of purity, free from the inert isomeride ergometrinine. It is isolated from the aqueous extract of ergot and characterised by the rapidity with which it causes uterine contraction.

Indicated after parturition, particularly in cases of collapse or anæsthetic sickness, in post-partum hæmorrhage, and in some cases of migraine.

Administration of the *pure* alkaloid is the only sure method of giving a known, adequate dose.

The accompanying kymographic tracings, taken during original work on the alkaloid, illustrate the action of ergometrine on the human uterus when used in effective doses.

INJURY AND INTERNAL DISEASE

BY

G. F. WALKER, M.D., M.R.C.P.

When a person alleges that a disease was brought on by injury truth may reside in one or other of the following:

TABLE I

(*a*) Injury may cause disease.
(*b*) Injury may precipitate disease.
(*c*) Injury may aggravate disease.
(*d*) Disease may promote injury (Ewing's "traumatic determinism").
(*e*) Injury may reveal disease.
(*f*) The association may be a pure coincidence.
(*g*) In post-traumatic debility and invalidism sundry maladies and degenerations may be installed.

In an assessment of any case certain minimal data must be forthcoming—namely:

TABLE II

(*a*) An authentic and tested statement of particulars of the injury.
(*b*) A full record of clinical chronology covering the pre-accident period, the injury, and the post-traumatic period.
(*c*) Accurate observation of all clinical phenomena, identification of the disease beyond all doubt, and a knowledge of the morbid processes at work.

With this framework we can first turn to the literature, and at once a few generalizations stand out:

TABLE III

(*a*) There is hardly any internal disease which has not by someone somewhere been attributed to injury.
(*b*) A very great deal of plagiarism and uncritical acceptance of authority has taken place.
(*c*) There is often a hopeless conflict of opinion between pathologists and clinicians.
(*d*) Many flimsy pieces of evidence have been copied from book to book for years.

Cancer

The first internal malady worthy of study is cancer, and here we are faced with conflicts of opinion. Briefly, three views can be found in the literature on the subject of injury causing cancer—namely: (1) Such an event is opposed to all known principles, but it may occasionally happen. (2) It not only may occasionally happen but in certain types of cancer it frequently does happen. (3) Wherever truth may lie between propositions 1 and 2, here, at least, is an authentic and well-tested case, or series of cases, without comment.

The main leaders of proposition 1 have been Phelps (1910), who, however, excluded sarcoma from his survey; Stephens (1928); Knox (1929), whose paper was an incisive and hostile counterblast to the writings of Coley; Mock and Ellis (1926); and more especially Ewing (1926, 1928).

As is well known, the chief exponent of proposition 2—namely, that injury is often associated causally with cancer—has always been Coley, who began his observations more than forty years ago. When Knox suggested that the protocols of Coley and others were nothing but a parcel of anecdotes and vague impressions Coley (1929) replied with the obvious retort that many authors make too great an effort to discredit the direct statements of intelligent patients. It is a fact that Coley's cases are always minutely described, and one often has a feeling that scepticism about his conclusions would be the very antithesis of science.

Class 3—namely, cases of post-traumatic cancer described by clinicians without comment—cause little difficulty. They are very scarce in medical literature as a whole. Among the best examples are those of Levy (1927) (sarcoma), Wainwright (1928) (carcinoma), Paul (1929) (rodent ulcer), Wells and Cannon (1930) (carcinoma of lung), Haler (1931) (sarcoma), Haler (1932) (sarcoma), Shaw (1935) (sarcoma), Willan (1930–1) (sarcoma).

The whole literature on cerebral tumour allegedly following injury was carefully reviewed by Marburg in 1934. The only possible conclusion from this typical pre-anschluss Viennese monograph is that head injury is extremely rare and unimportant as a cause of cerebral tumour. Parker and Kernohan (1931) found in a series of 431 cases of glioma of the brain that 58 (13.4%) reported injury as a cause. In a series of 431 patients without tumours of the brain there was a history of injury to the head in 45 (10.4%). In 200 normal persons 71 (35.5%) reported injury to the head. On further examining the 58 the history could be disregarded in all but 21—i.e., 5%.

Lastly, in the matter of comparative pathology it is very notable that Volume XCIII, 1931, of *Annals of Surgery*, which was devoted to an international study of cancer, contained little or nothing about acute traumatic malignancy. Slye (1931) recorded observation on seemingly very quarrelsome mice. Of 14,000 necropsies on these animals, 1,301 showed indisputable neoplastic growths. Of the 1,301, 51 arose under observation at the sites of recorded gross trauma sustained in fighting. Slye thought little of this, but believed more in heredity and gave good reasons.

Organic Nervous Disease

We can now pass to a consideration of organic nervous disease, exclusive of epilepsy and mental disorder, which will be dealt with later.

Here again three types of views are discernible in the very extensive literature—namely: (*a*) Trauma plays no part at all in the installation of organic nervous disease. (*b*) In certain cases trauma is the decisive precipitating factor. (*c*) Wherever truth may lie between *a* and *b*, here is a thought-provoking case.

The great authority of Kinnier Wilson (1923) stands behind proposition *a*. Addressing the American Medical Association at San Francisco in 1923, he expressed himself as hostile to the notion that trauma might initiate morbid neurological processes, especially progressive lesions. He denounced suggestions of the existence of traumatic cerebral tumour, but grudgingly admitted that a few cases of disseminated sclerosis and a very few cases of tabes and dementia paralytica might seem to be initiated by trauma. Very similar views have been expressed by Crouzon (1931), Jelliffe (1935), and many others of less standing.

There is a very rich seam of literature in support of proposition *b*—namely, that trauma may in certain cases initiate organic nervous disease. Harris (1933) quotes what he calls the "astounding difference" in the views given on the traumatic factor in progressive muscular atrophy in the second and the fourth editions of Price's *Textbook of Medicine*, and points out the fallacies of condemning the possibilities of trauma. He quotes his own cases in great detail, and these support proposition *b*. Harris sums up his personal experience as follows: "My own view is that when symptoms develop directly after an injury in a previously healthy individual we have no right whatever to assume that the injury has no causal connexion with the development of the disease." Very similar views were expressed by Hinds-Howell (1932) and Garland (1938).

Coming to proposition *c*—namely, simply recorded cases—we find the following: Jelliffe (1935) reported one case (not seen by him) of alleged traumatic amyotrophic lateral sclerosis together with some learned comments on contradictions and evasions by neurologists. The bulk of his paper is a summary recapitulation of 90 similar cases from the literature with comment such as "doubtful" or "too remote," but no substantial discussion. In another further study of alleged traumatic amyotrophic lateral sclerosis Waggoner and Löwenberg (1939) published a remarkable case of a patient exhibiting *both* amyotrophic lateral sclerosis due to natural causes and a traumatic syndrome resembling amyotrophic lateral sclerosis. Elkington (1936) examined and reported on 41 cases of meningitis serosa circumscripta. He believed trauma to be the cause in 9. As for progressive muscular atrophy, Sutton (1938) recorded one case on rather attenuated evidence, and Walker (1938) mentioned four cases, in only one of which the traumatic cause was accepted without question by the party liable to pay compensation. Turner (1939) made a very careful survey and concluded that trauma might initiate progressive muscular atrophy in a certain small proportion of cases.

There are on record any number of cases of Parkinsonism allegedly due to trauma, and among the best examples are: Pommé and Liégeois (1931), following head injury; Ramond (1935), following concussion; Weinberg (1939), 2 cases following electric shock; Patrick and Levy (1922), general review; Grimberg (1934), head injury; Kulkov (1932), head injury; Bruetsch and De Armond (1935), head injury; Faure-Beaulieu (1932), peripheral injury; Naville and de Morsier (1932), review of 42 cases following peripheral injury; Hodgson (1937), peripheral gunshot wound; Walker (1937), peripheral industrial accident.

There is one other disease which I have always thought nervous rather than "rheumatic." I mean chorea. In 1934 I found myself in possession of minute notes of 200 cases of chorea, personally observed. In these 200 I found 26 definitely initiated by physical injury such as a scald, lacerated scalp, injuries in a fire, severe caning, dog-bite, etc. (Walker, 1935).

Myocardial and Pericardial Lesions

A very learned monograph on myocardial and pericardial lesions alleged to follow non-penetrating trauma was written by Warburg of Copenhagen in 1938. It is very interesting to peruse the reviews of this little book. In England the *Lancet* (October 22, 1938) was friendly, noncommittal, and uninformative, while the *British Medical Journal* (November 12, 1938) was hostile, critical, and sceptical about Warburg's conclusions. On the other hand, the *Journal of the American Medical Association* (November 12, 1938) willingly accepted Warburg's conclusions that blunt non-penetrating trauma to the chest may indeed install myocardial disease. The subject has been reviewed in modern fashion by Barber (1940), whose notes and references set out a clear exposition. Case records especially worthy of study (in addition to those quoted by Barber) are those of Kahn and Kahn (1929); Kahn (1930); Levison (1927); and Elkin (1935). The case which is reported by Priest (1939) is an especially interesting and curious one. The paper by Hay and Jones (1927) purporting to show the installation of auricular fibrillation by trauma met with severe criticism in that many cardiologists in effect insisted that the cases did not fulfil the requirements laid down at the beginning of this paper (Table II).

The best recent review of coronary disease and angina following strain or inordinate exertion is that of Boas (1939), who showed the relationship clearly in an admirably careful survey of 14 cases.

Mental After-effects of Head Injury

A consideration of the mental after-effects include a review of the literature on traumatic epilepsy, late traumatic apoplexy, psychosis, and chronic subdural haemorrhage. These are here considered in turn:

Of traumatic epilepsy Stevenson (1931) wrote:

> "The term 'traumatic epilepsy' should be limited to cases of epilepsy resulting from injury to the brain or its membranes. The term 'Jacksonian epilepsy' should be applied only to localized fits of cortical origin. . . . Traumatic epilepsy may develop as late as ten years or more after severe injury of the head, but usually there has been in the interval vertigo, paroxysmal headache, or other premonitory symptoms. Epilepsy following superficial wounds of the head is most often psychogenetic in origin. . . . The fits in traumatic epilepsy are, in most cases, clinically the same as in idiopathic epilepsy. Both major and minor attacks occur. Vertigo and mental deterioration are both more common in traumatic epilepsy than in idiopathic."

Similar observations can be found in the writings of Symonds (1935), Turner (1923), Wagstaffe (1928), and Elvidge (1939). Finally, Foerster and Penfield (1930) stressed the part played by progressive intracerebral scar formation.

The very large amount of literature on late traumatic apoplexy has been ably surveyed by Symonds (1940).

The literature on mental disturbance following head injury is truly formidable. Most papers are modelled on that of Mickle (1892), who recognized as possible sequelae

to head injury: (*a*) psychoneurosis, such as automatism, stupor, melancholia; (*b*) paranoia; (*c*) organic disease, with dementia; (*d*) functional disturbance. At the B.M.A. Meeting at Cardiff in 1937 the mental effects of head injury formed a topic of important discussion. Mapother (1937) referred to the lack of unanimity among authorities and the different views held by civil and military experts. He quoted a series of 5,000 private patients, of whom 123, or possibly slightly fewer, owed mental disorder to head injury. Other speakers mentioned the following possibilities:

(*a*) Pre-existing mental instability disposes to gross hysterical manifestation after head injury.

(*b*) Persons of cyclothymic or manic-depressive mental constitution are prone to an attack of depressive psychosis after head injury.

(*c*) Subarachnoid haemorrhage must always be considered in cases of mental disorder following head injury. Similarly, cerebral oedema often plays a part.

(*d*) Much vague mental disorder after head injury could be prevented by clear, decisive, prompt, and positive clinical and legal handling of the patient.

(*e*) Howsoever they arise (and much is obscure) schizoid psychoses are common sequels to head injuries.

Of "chronic subdural haemorrhage" there is little to be said beyond what Trotter (1914) originally stated. He defined the illness as consisting of a relatively mild injury, a latent period, headache, drowsiness, and remarkable transitions between full consciousness and coma. A very good recent summary, well illustrated, is given by Fleming and Jones (1932) with details of 8 cases. Another review of 22 cases is that of Gardner (1935). Other literature of importance is: Pearson (1928), head injury in two boys (sequel in each case was a regression to the symptoms and behaviour of an illness each had had in infancy); Mock (1929), similar to Mapother; Le Fevre (1933), morbid anatomy; Hoch and Davidoff (1939), role of previous personality in the development of traumatic psychosis.

Injury to Bones and Joints

The best recent summaries of disease processes induced by injury in bones and joints were given by Buchman (1929) and Brailsford in 1936. The latter stated that he was familiar with localized rarefying osteitis or "osteochondritis" in 21 different sites, and said: "After carefully weighing the evidence obtained from over 100 cases personally observed, I am of the opinion that trauma is the exciting cause of these conditions, but in view of the fact that it is the minority only of the cases of trauma in which the sequence of characteristic changes develop, I feel that there must be some other contributory factor."

Two post-traumatic osseous maladies call for special mention. The first is osteochondritis dissecans, and it is quite noteworthy that König, who first described this in 1888, and Burr, who followed with a modern description in 1939, both thought that trauma was not solely responsible. However, Fairbank (1933), in a very careful survey, said he believed that osteochondritis dissecans of the knee (the usual site) was caused by trauma "pure and simple," and he explained the mechanism as violent rotation inwards of the tibia, driving the tibial spine against the inner condyle. Monteith (1934) published a remarkable case in close support of this. Funsten and Kinser (1936) reported a substantial series of cases showing the preponderating influence of trauma and the appearance of osteochondritis dissecans in sites other than the knee.

The second malady is post-traumatic osteoporosis, which, if accompanied by pain, swelling, and vasomotor disturbance, is sometimes called Sudeck's atrophy. Good accounts of this have been published by Gurd (1935)—24 cases beautifully illustrated; Leriche and Fontaine (1936a, 1936b)—16 cases, also beautifully illustrated; Middleton and Bruce (1934)—7 cases; Middleton (1937)—full clinical description; Beyer, 1938; and Simpson (1937)—a very obscure and unusual case of painless decalcification.

Diabetes Mellitus

Trauma and diabetes mellitus furnish a very rich and contradictory literature. I recently published a case (Walker, 1940) of diabetes mellitus which I thought was directly and solely due to injury. The whole of the literature, and all ideas hitherto expounded on this problem, were summed up in a very lengthy general survey written by Viggo Thomsen in 1938. The author minutely examined 81 cases hitherto published as "traumatic diabetes" and brought forward a large series of highly controlled observations on the changes in carbohydrate metabolism following accident in normal and glycosuric patients. He concluded a very just and erudite monograph with a denial that trauma could ever cause diabetes mellitus. This view had the honour of laudatory acceptance in an unusually long editorial leading article in the *Journal of the American Medical Association* of April 22, 1939, but there remain clinical problems and recorded cases which Thomsen leaves utterly unsolved. It is noteworthy that all Thomsen's work was done before the part played by the pituitary was fully realized. Pedrazzini (1939) expressed conviction that true diabetes mellitus may be precipitated by any kind of injury, and gave fair evidence.

Tuberculosis

The installation of tuberculosis by trauma may take one of four forms, according to May (1928). He recognized: (*a*) recrudescence of a pre-existing focal tuberculous lesion; (*b*) miliary tuberculosis following trauma at the site of a tuberculous focus; (*c*) tuberculosis arising at the site of an injury without history of previous tuberculous disease; and (*d*) phthisis after a non-thoracic injury. Very much more detailed and attractive propositions have been published by Oliver (1915), who gave four seemingly clear cases of post-traumatic phthisis; Tattersall (1922), who described two very convincing cases; Tattersall (1928), who surveyed 300 cases of phthisis, with an authentic history of provocative injury in 4; Stoichitza (1934), who gave an account of two cases of traumatic phthisis and himself described the evidence as "clear, precise, and irrefutable"; and Mayer (1935).

Other Conditions

Leukaemia.—Trauma as a cause of leukaemia has been described by Lewsen (1930), Weil and Bousser (1936), and more particularly by Olovson (1939), who reviewed all published cases and added two of his own. Olovson was disposed to think that trauma may well precipitate myeloid leukaemia in a person already disposed to it.

Appendicitis.—Trauma as a factor in acute appendicitis has been described by Ludington (1923), Behan (1927), and Bissell (1928). The cases described by the last-named are much more credible than the single case described by Ludington. Very lengthy reviews and commentaries were made by Fowler in 1938 and Grettoe in 1939. The conclusion from these five authors is that "it may occasionally happen." Recent cases of traumatic appendicitis include those of Burgess (1938), Rogers (1938), and Goodyear (1938). A great deal of correspondence followed these cases, and the *Journal of the American Medical Association* (June 4, 1938) gave the view, cautiously, that trauma may indeed provoke appendicitis, usually of a grave and fulminating type.

Gastro-duodenal Ulcer.—No paper of this type would be complete without reference to gastro-duodenal ulcer.

Although textbooks of medicine and surgery often mention trauma vaguely in discussing the cause of these maladies, no sets of authentic cases have recently been recorded. But in this connexion, as also in connexion with perforation, many authentic cases are on record in which the stomach has been ruptured by external violence without gross evidence thereof.

Pneumonia.—The possibility of trauma causing pneumonia is always mentioned in textbooks of medicine. It has been referred to over and over again in successive editions of Osler's *Principles and Practice of Medicine.* According to Brockbank (1926) the possibility was known to Morgagni. It was well known to Allbutt, according to his *System.* Several authors mention Litten's series and Stern's series, but I have not found these in the original. On the other hand, Rufus Cole of the Rockefeller Institute, according to his article in *Nelson's Loose Leaf System,* saw 700 successive cases of pneumonia without any trace of trauma at all.

Syphilis.—Trauma in a syphilitic may determine the site of syphilitic lesions in almost all organs of the body. Cases were given by Klauder (1922) as follows (all in proved syphilitics): gumma at the site of a laceration; gumma at site of repeated trauma; gumma of testicle after trauma; change of a negative Wassermann reaction to positive again as a result of trauma (2 cases); aneurysm developing suddenly after violent physical effort; delayed recovery from lacerations; paresis following head injury (3 cases).

At the beginning of this paper I mentioned that there is hardly any disease which has not at some time or other been attributed to trauma. A few case records deserve mention:

Sundt (1921). Trauma as a predominant agent in many cases of pseudo-coxalgia.

Platt (1922). Dissents from Sundt.

Vance (1923). Traumatic lesions of the intestine caused by non-penetrating blunt force.

Hartley (1923). Similar to Sundt.

Moersch (1926). 2 cases of diffuse cerebral gliosis seemingly caused by concussion.

Buchman (1928). Osteoporosis of the carpal bones. (Clinical descriptions not to be found elsewhere.)

Sargent and Greenfield (1929). Close relationship between cranial trauma and haemangiomatous cysts of the cerebellum.

Bolton (1929). Rupture of the stomach from external non-penetrating violence with no sign of external injury.

Chandler (1931). 11 cases of spondylolisthesis (in a series of 18) in which trauma seemed to initiate the symptoms.

Kendall (1931). Traumatic nephrolithiasis.

Mouat, Wilkie, and Harding (1931). Importance of injury in Kienböck's disease.

Capener (1932). 9 cases of spondylolisthesis (in a series of 34) giving a history of injury.

Royal Society of Medicine (1933). Traumatic Argyll Robertson pupil.

Chandler (1934). Bilateral suprarenal apoplexy due to trauma.

Dodd (1934), Gardiner (1935), Hunter (1935). Ruptured spleen after trivial mishaps.

Cooke (1934). Traumatic rupture of lungs without signs of trauma in the chest wall.

Bramwell (1934). Auricular fibrillation caused by head injury.

Fagge (1934). Fatal ulcerative colitis following head injury.

Edström (1936). Five cases of rheumatic fever beginning at or near an injured joint.

Hill (1936). Traumatic oedema.

Muller (1937). Post-traumatic renal stone (in colliery and street accidents).

Thomson (1938). Sudden post-traumatic senility.

Moritz and Wartman (1938). Four cases of post-traumatic internal hydrocephalus.

Meyerding and Pollock (1938). March fracture. (A very full and useful account of a malady now reappearing.)

Monteith (1938). Myositis ossificans with favourable course.

Bedell (1939). Traumatic retinal angiopathy (not necessarily head injury).

Fallon (1940). Lung injury in an intact thorax.

Findlay and MacCallum (1940). Recurrent traumatic herpes.

REACTIONS AFTER TRANSFUSION OF STORED BLOOD

BY

ERIC C. O. JEWESBURY, B.M., M.R.C.P.

Chief Assistant, St. Bartholomew's Hospital; sometime Medical Officer to the North-East London Blood Supply Depot

The transfusion of stored blood for many conditions has now become an established practice, and it may therefore be worth while to record some observations made on the incidence of reactions after its use.

Reliable statistics about reaction rates both from stored and from fresh blood transfusions are exceedingly difficult to obtain, mainly because there is little uniformity of opinion as to what constitutes a "reaction." Moreover, the reaction rate will vary with the person who carries out the transfusion, the method employed, the rate of administration, and the condition of the patient. Two disasters which cannot rightly be termed "reactions" but which may develop equally after the use of either fresh or stored blood result from an incomplete understanding of the technique of blood transfusion. They are: (1) pulmonary oedema with cardiac failure, due to overloading of the circulation of a patient whose heart is already embarrassed; and (2) renal failure due to transfusion of blood of an incompatible group. The more usual type of reaction that is apt to occur after a blood transfusion is a febrile reaction. It is unnecessary here to discuss the theories of the causes of such a reaction, although it is generally thought that the introduction of foreign protein into the blood stream plays an important part.

Reactions after Transfusion of Fresh Blood

The febrile reaction may be of variable severity. A simple rise of temperature without shivering or rigor is exceedingly common. Kordenat and Smithies (1925) maintain that nearly all transfusions of fresh blood are associated with some rise of temperature, even though this may be symptomless. Riddell (1939) is in agreement with this statement. Other observers believe that about 50% of fresh blood transfusions are associated with a rise of temperature or a rigor. A mere rise of temperature without constitutional effects is of little significance, but a rigor is more distressing and may even precipitate cardiac failure.

In considering the incidence of transfusion reactions, therefore, it is necessary that the reactions be divided into grades. The following classification is made by Riddell: *Grade I*, associated with a rise of temperature to 100° F., but no other objective features. *Grade II*, associated with a similar or greater rise of temperature and subjectively with feeling cold and shivery, but without having an actual rigor. *Grade III*, associated with a definite rigor. Riddell, giving his figures for his last 100 transfusions with fresh blood, noted rigors (Grade III reaction) in 11%. Fell (1938), analysing 500 cases, found reports of rigors in 4.8%. Edwards and Davie (1940) gave the following statistics of reactions after 100 consecutive transfusions of fresh citrated blood at the Liverpool Royal Infirmary: none, 37%; doubtful, 15%; Grade I, 15%; Grade II, 25%; Grade III, 8%. Grade III reactions are the most striking and easily recognized. Their average incidence in these three careful investigations on the use of fresh blood is 7.9%.

Reactions after Transfusion of Stored Blood

Edwards and Davie report that out of 1,364 bottles of stored blood administered by numerous surgeons in a variety of hospitals 69 (5%) gave rise to a Grade III reaction. These and other results with preserved blood, some of which are quoted by them, are tabulated below:

	No. of Transfusions	Grade III Reactions
Liverpool Royal Infirmary (Edwards and Davie, 1940)	1,364	5.0%
Milton Road Infirmary " "	—	4.0%
Walton Hospital " "	—	12.0%
Lundy, Tuohy, and Adams (1937)	149	4.2%
Cameron and Ferguson (1939)	1,000	2.8%
Elliott, Macfarlane, and Vaughan (1939) ..	50	8.0%
Hamilton-Paterson (1939)	46	6.0%
Biddle and Langley (1939)	150	5.0%
DeGowin and Hardin (1940)	1,453	3.9%
Brewer, Manzels, Oliver, and Vaughan (1940) ..	56	5.4%

The average incidence of Grade III reactions in all these transfusions with stored blood is 5.6%.

In order to determine the reaction rate and other results of the use of stored blood from the North-East London depot a label was attached to every bottle of blood sent out. This label consisted of a detachable reply-paid postcard which the medical officer who gave the transfusion was asked to fill in and return. Investigations suggest that in perhaps half of the transfusions carried out this request was complied with. The first 700 labels returned have been analysed, with the following results:

TABLE I.—*Results of Transfusion of 700 Bottles of Stored Blood. Average Age of Blood, 10.8 Days*

No. of transfusions	389	
Grade I reactions	44 (11.3%)	
" II "	17 (4.4%) } 8.5%	= 19.8 per 100 transfusions
" III "	16 (4.1%) }	
Jaundice	6 cases	= 0.86%
Urticaria	4 cases	= 0.57%

Riddell's classification was slightly modified in that Grade I reactions were those in which any rise of temperature above 99° F. was reported but in which there was

no shivering or rigor. Grade II reactions included shivering attacks and mild chills. Grade III reactions were obvious rigors.

Thus the total incidence of Grade II and Grade III reactions was 8.5%, while marked rigors (Grade III reactions) occurred in only 4.1% of cases. These results compare favourably with those of the transfusion of fresh blood to which reference has already been made.

Because of the unreliability of statistics based on a comparatively small total number, and because of the uncertainty as to the proportion of labels that were returned after transfusions, each group of 100 labels was analysed separately, and it will be seen that the figures in each group are in fairly close agreement with each other (Table II). Each bottle contained 360 c.cm. of blood and 180 c.cm. of anticoagulant fluid (composed of 1.05% sodium citrate and 3% glucose in 0.85% sodium chloride solution). The Medical Research Council depots are now using a modification of this mixture (see M.R.C. War Memorandum No. 1, 1940).

TABLE II

Hundred Bottles:	First	Second	Third	Fourth
No. of transfusions	62	63	57	52
Grade I reactions	14.5%	14.3%	12.3%	7.7%
,, II ,,	1.6% } 6.4%	4.8% } 6.4%	5.3% } 8.8%	3.8% } 11.5%
,, III ,,	4.8%	1.6%	3.5%	7.7%
Total	20.9%	20.7%	21.1%	19.2%
Average age of blood	8.3 days	9.6 days	9 days	10.5 days

Hundred Bottles:	Fifth	Sixth	Seventh
No. of transfusions	52	49	54
Grade I reactions	11.5%	10.1%	7.4%
,, II ,,	5.8% } 5.8%	0 } 4.0%	9.3% } 16.7%
,, III ,,	0	4.0%	7.4%
Total	17.3%	14.1%	24.1%
Average age of blood	13.5 days	11.5 days	13.3 days

These findings bear out the opinion of other investigators such as Biddle and Langley, who state: "We are well satisfied that stored citrated blood produces no more complications than does fresh citrated blood, and the advantages of the former cannot be exaggerated." DeGowin and Hardin (1940) state that, in their experience, "no types of reaction were observed from the transfusion of preserved blood which were not already known to be associated with the use of fresh blood. . . . The incidence of various types of reaction did not increase or decrease with the period of storage of the blood mixtures."

In my own series 58 of the bottles of blood were 21 or more days old, but the average age of the blood causing Grade II reactions was 13.4 days, while the average age of the blood causing Grade III reactions was 12.7 days. Reactions were by no means confined to the older blood. Thus, shortly after receiving one bottle of 3-day-old blood one patient had a rigor for ten minutes with a sense of constriction in the chest and headache. On the other hand, two bottles of 21-day-old blood and one bottle of 28-day-old blood were given to another patient without any reactions developing. The oldest blood used consisted of two bottles that had been stored for 33 days. This was given to a patient with salpingitis and a urinary infection whose haemoglobin was 59%. There was no reaction or discomfort during the transfusion, but one hour afterwards she had a rigor. Her temperature fell to normal within forty-eight hours and remained so. There was no jaundice or other untoward reaction, and her haemoglobin had risen to 71% the day following the transfusion. Eight days after the transfusion she was given another bottle of blood—this time 28 days old. There was no rigor or discomfort on this occasion. Her temperature rose slightly (to 99.4° F.) in the evening, but the next day and thereafter it remained normal.

The 4 cases of urticaria resulted from transfusion of blood stored for 1 day, 3 days, 12 days, and 19 days. The six cases of jaundice, however, seemed to be the result of transfusion of somewhat older blood, since in all but one instance it had been stored for 14 or more days.

Red Cell Destruction

Since even fresh blood contains many aged erythrocytes, rapid destruction of these is to be expected after their transfusion. When stored blood is used the degree of destruction increases with the age of the blood. These facts have been demonstrated by Ashby's (1919) method of estimating cell survival after transfusion. Maizels and Hamilton-Paterson (1940) have found, however, that when the blood had been stored for 7 to 14 days more than 75% of the cells survived in the patients' blood stream after six days, and in some instances transfused cells were found months after transfusion. Mollison and Young (1940) found that when blood over 20 days old was transfused a great deal of destruction took place within a few hours of transfusion, although the time taken for the complete disappearance of the transfused cells was little less than that found for fresh blood.

It thus appears that the rapid initial fall in the number of transfused cells of stored blood is due to the destruction of effete corpuscles and that those that do not quickly succumb are relatively resistant to haemolysis. The early destruction of effete cells results in a transient increase in the bilirubin content of the patient's plasma and the presence of urobilin in the urine. If the amount of red cell destruction is excessive the patient may become jaundiced, but this is of very brief duration, since the excess of bilirubin is rapidly removed from the blood stream.

Using the preservative solution described it is found that most of the degenerative changes in the blood, other than the disintegration of the red cells, occur within the first two weeks of storage. Up to three weeks the amount of *in-vitro* haemolysis is negligible. The subsequent amount of haemolysis in previously undisturbed blood, estimated by the method described by Hudson (1940), was as follows:

TABLE III

Length of Storage	Average Haemolysis	No. of Bloods Examined
3 weeks	1.0%	9
4 ,,	2.9%	12
5 ,,	3.8%	13
6 ,,	8.1%	7

Further haemolysis is likely to occur when the stored blood is transfused into a patient, and this can be shown by pipetting off from a centrifuged specimen all the supernatant plasma and replacing it by isotonic saline or fresh normal serum. If this is gently mixed and allowed to stand or is centrifuged, considerable additional haemolysis is observed, and it is found on measurement to be more than that in the original plasma.

It is therefore important as a routine not to use blood preserved under present conditions for more than three weeks, since the haemolysis both *in vitro* and *in vivo* may result in transient jaundice and possibly be the cause of other reactions. Bushby, Kekwick, Marriott, and Whitby (1940) have proved that the increase in plasma bilirubin of the recipient is due not to free haemoglobin in the transfused specimen but to *in-vivo* haemolysis of transfused cells. Amberson (1937) concluded that haemoglobin is not toxic to vertebrates if it has been properly freed from stroma, and Duesberg (1934) has injected haemoglobin intravenously into man in amounts varying

from 2 to 6 grammes without ill effect. Hamilton Fairley (1940) has successfully injected considerably larger amounts after careful alkalinization of the urine.

It is therefore likely that the febrile reactions after transfusion of very old blood are due to products of red cell disruption and degeneration rather than to the mere presence of free haemoglobin in solution.

Though it is not relevant here to discuss the merits of various preservative solutions it is important to use mixtures that are most likely to prevent the early breakdown of the red cells. That haemolysis is impeded by the presence of glucose is now well known. Table IV shows the average haemolysis in five samples of blood, each preserved with and without glucose, over a period of six weeks.

TABLE IV.—*Comparison of Haemolysis with and without Glucose*

Weeks	With Glucose	Without Glucose
3	0.91%	4.99%
4	1.76%	13.24%
5	3.46%	24.75%
6	8.17%	37.4%

Blood preserved in solutions containing no glucose might therefore be expected to lead to a greater incidence of transfusion reactions owing to the additional *in-vitro* and *in-vivo* haemolysis, and this has been found to be so. Thus in the transfusion of fifty bottles of blood preserved without glucose the results of transfusion were as follows:

TABLE V.—*Fifty Bottles of Blood Preserved without Glucose. Average Age of Blood, 11.1 Days*

No. of transfusions	33	
Grade I reactions	18.2%	
,, II ,,	15.1% } 27.2%	= 45.5 per 100 transfusions
,, III ,,	12.1%	
Jaundice		1 case = 3%
Urticaria		1 case = 3%

The total number of bottles of non-glucose blood used is not large, but the reaction rate is considerably higher than in any group of 100 bottles of blood preserved with glucose.

Stored blood can never be better than fresh blood, but its ready availability is an immense advantage, particularly in an emergency, and this outweighs any slightly smaller rise of haemoglobin percentage in the recipient that may occur. The disadvantage of stored blood has been seen to resolve itself chiefly into the question of haemolysis, but with modifications of the preservative solution the life of the red cells can be further prolonged. Fortunately there is now less need to attempt to preserve emergency supplies of blood for long periods of time, since plasma or serum, capable of independent storage for many months, can be given as an emergency measure in place of whole blood in certain cases, when whole stored blood is not immediately available.

Conclusions

There is no significant difference in the nature or number of reactions which tend to occur after the transfusion of fresh blood and blood stored up to three weeks under standard M.R.C. conditions. Such difference as may occur seems to be in favour of stored blood.

When standard stored blood is used a febrile reaction is to be expected in about 20% of transfusions and an obvious rigor in about 5%.

The incidence of jaundice and febrile reactions tends to increase when blood more haemolysed than this is used. These reactions appear to be caused not so much by the free haemoglobin introduced as by the early disruption of effete red cells after transfusion.

Stored blood, as originally prepared, can safely be used for three weeks and in some cases for longer. Modifications of the preservative solution may further increase the useful life of the blood, though the introduction of preserved plasma and serum now renders this less necessary.

I am grateful to Dr. H. F. Brewer, Director of the North-East London Blood Supply Depot, for facilities in making these observations, and to the Medical Research Council for helpful criticisms of the paper.

CARRIERS OF TUBERCULOSIS

BY

JAMES MAXWELL, M.D., F.R.C.P.

Assistant Physician, St. Bartholomew's Hospital; Physician, Royal Chest Hospital

The fact that many infectious diseases may be contracted from contact with individuals who are not themselves suffering from any of those diseases at the time of contact is well known. Typhoid fever, scarlet fever, and some other streptococcal infections, cerebrospinal fever, diphtheria, and acute poliomyelitis are examples that come to mind at once, but there may be many other diseases which are spread in this way. The exanthemata and even the common cold, though usually contracted in epidemics from known sources, sometimes appear in a sporadic form which suggests the possibility of contact with a carrier.

Types of Carrier

Clinically there are two types of carrier—the known and the unsuspected. A known carrier has had the disease in question and has never been shown to become bacteriologically negative, although he no longer suffers in any way from the infection; in such a case the organisms appear to be saprophytic only. Carriers of this type are usually kept under observation until eventually the organisms are eradicated by some means or other; in any case they are a known danger and can therefore be controlled to some extent. The unsuspected type of carrier is much more dangerous, for his very existence may not be even suspected until extensive damage has been done. Such persons may have had their infection in an abortive or aberrant form, the true nature of which was not recognized at the time, or, more difficult still, they may never have had the disease in their lives so far as the most careful clinical investigation can discover.

In view of the great amount of work which has been done on the carrier problem it is surprising to note that little attention has apparently been paid to the possibility of the existence of carriers of tuberculosis. Of course it is well known that sufferers from chronic pulmonary tuberculosis may eject tubercle bacilli in the sputum for years, but a point often overlooked is that those who have

ceased to suffer from the complaint—i.e., patients whose disease has been classed as and is in fact "arrested"—may do the same thing, either continuously or at intervals. Such patients may be perfectly fit in the physical sense, and every possible test which can be applied to detect the presence of tuberculous toxaemia or of progressive change in the lungs may be negative. There may be no fever even on great exertion, the weight may be steady and satisfactory, there may be no sputum except when a cold or a mild bronchial infection causes slight expectoration, the sedimentation rate may be normal, and the radiographs may show very little damage or, at any rate, no appreciable change over a period of years. It is likely that many individuals who are quite unaware that there is anything at all wrong with their lungs may be coughing up tubercle bacilli from time to time; it is even possible that this also occurs in the case of some in whom no amount of investigation would reveal any trace of disease. The existence of cases in this latter group would be very difficult to prove, for it would mean the wholesale examination of the sputum, almost on a national scale. The fact that, even to-day, phthisis is being recognized as such for the first time in persons who have had cough and sputum for many months, or even for years, suggests that neither the public nor the medical profession are yet educated to the proper standard in the application of this simple test.

The subject of pulmonary tuberculosis is of particular and pressing interest at the present time, both because of the care which has to be taken in order to exclude cases with early disease from the Forces and because of the risk of spread of the infection which is likely to result from contact in air-raid shelters. Much has been written about mass radiography; this is certainly desirable, and the results already have been of considerable value. But it must be remembered that radiographs demonstrate shadows only, and that the information gained solely refers to anatomical change in the tissues. Infectiousness is an entirely different problem, but it is one which is even more important, for it concerns that part of the population which is still not infected, and not a particular individual. The only test of the infectivity of any person is the examination of the sputum. It is not suggested that mass sputum examinations should replace mass radiography, but it seems necessary to point out that these examinations are of immeasurably greater value if both are considered together, and that a complete observation should therefore always be made when looking for tubercle.

Danger of Apparently Healed Cases

The object of the present paper is to point out that apparently completely healed cases of tuberculosis may still constitute a danger to the public health, and to suggest that the disease may even be spread by contact with people who themselves appear to be perfectly normal. While the second part of this thesis is likely to be difficult to prove, four cases are reported in which the disease showed not the least sign of activity and yet the patients were certainly infectious from time to time.

Case 1.—A widow aged 65 came to the out-patient department of the Royal Chest Hospital in 1929 complaining that she had suffered from cough, a little sputum, and increasing shortness of breath for the past three winters. On examination she appeared to be a typical chronic bronchitic. The past history was most instructive. She had had eleven children, of whom no fewer than six had died in infancy from acute forms of tuberculosis. In addition two grandchildren had died from the same complaint. The sputum was negative for tubercle bacilli, but the radiograph showed several small calcified deposits in both upper lobes. On careful questioning she would not admit to any previous period of illness in her life. It seemed perfectly clear that this woman had suffered from tuberculosis in a subclinical form, and that she had been a menace to her family for a considerable period of time.

Case 2.—A retired business man aged 80 was seen in consultation in 1938. His complaint was that he had become rather wheezy during the last three years and found it difficult to manage a complete round of golf, although he was still capable of playing nine holes without undue fatigue. In his case a diagnosis of active tuberculosis had been made in 1888, and tubercle bacilli had been found in the sputum at intervals since that time, although he had led a normally active life. Tubercle bacilli were still present in 1938. On examination there was evidence of fibrosis in both upper lobes, and this was confirmed by radiograph; there was, however, not the least evidence of active disease, and one had the impression that the condition had been stationary for a long time, although it was not possible to prove this as the previous films were not available for comparison. There was, however, evidence that the patient had been coughing up bacilli for half a century, and his clinical state appeared to indicate that the disease had not been progressive for many years. This case illustrates the type of carrier who has made a clinical recovery from the disease but has never become bacteriologically free.

Case 3.—A nursing sister aged 35 complained of a slight cough. In 1929 her sputum was slightly stained on three occasions. No records are available of the condition at that time, but a right artificial pneumothorax was induced and was kept up for two years, when it had to be abandoned owing to obliterative pleurisy. Since that time she had been nursing in a sanatorium and had apparently been in good health. In January, 1940, there was again slight staining of the sputum following a cold, and re-examination showed the presence of a few tubercle bacilli. There were no abnormal signs in the chest, and the radiograph showed only a little thickening of the pleura overlying the right lower lobe, consistent with the old obliterative pleurisy. So far as could be determined the lung fields themselves were normal and a tomogram did not reveal anything further. Between January and July the sputum was found to contain tubercle bacilli on three occasions, although it was negative on several others. In April, 1940, she was admitted to the Royal National Sanatorium, Bournemouth, where the sputum was found to be positive on two occasions. She was not complaining of any symptom except a slight cough with a minimal amount of sputum; her general condition was excellent; there were no abnormal physical signs, the radiograph showed nothing beyond slight pleural thickening over the right lower zone, and the sedimentation rate was 4 mm. in one hour. After keeping the patient under observation for some weeks it seemed impossible to conclude that she was suffering from active tuberculosis as the term is generally understood, and the view was taken that she was in fact a carrier of the disease.

Case 4.—A single woman aged 25 came to the out-patient department of the Royal Chest Hospital in 1932 "for an overhaul." Her brother had died from pulmonary tuberculosis two months previously. The patient appeared to be in perfect health, and physical examination was entirely negative. A radiograph of the chest showed nothing abnormal, but the sputum was reported to contain tubercle bacilli on two occasions, although many other tests proved negative. This patient was kept under observation for two years, during which time her condition remained unchanged and she appeared to be in perfect health. The sputum tests were carefully carried out and there does not seem to be any reason to consider that they were not genuine.

Discussion

These four cases are recorded in order to stimulate further investigation into the infectivity of tuberculosis among members of what appears to be the normal population. Naturally the cases described have been chiefly those in which there had been some story of contact with the disease to account for tubercle bacilli being looked for. In none of them, at the time of examination, could it be said that the patient was suffering from active tuberculosis, yet three were infectious and the fourth had clearly

infected others in the past. The diagnosis of pulmonary tuberculosis rests upon a correlation of symptoms, signs, radiological appearances, and pathological tests. No single one of these can be regarded as sufficient in itself for an assured diagnosis. It appears certain that, without confirmation from these other sources, the presence of tubercle bacilli in the sputum cannot be regarded as proving the contention that there is active disease. In other words, the expectoration of tubercle bacilli may be consistent with clinical health for a long period of time, and persons so expectorating may well act as carriers of the disease. Although not illustrated in this series of cases, it is quite likely that some of the patients who harbour the bacilli in their respiratory tract in this way are liable to relapse and to sustain further spread of the infection in their lungs.

The fact that these cases are infectious is a matter of great importance from the public health point of view Sometimes they are sent to a sanatorium; but sanatorium treatment is not likely to sterilize the respiratory tract, and actually we do not know of any measures that will render such a patient free from bacilli. Steps can be taken to make them as safe as possible by ensuring that they observe the same precautions as do other patients discharged from sanatorium with a positive sputum, the chief difference being that they can lead a normal life without restrictions.

Summary

This paper is not intended as a record of fresh observations, but rather as a presentation of known facts from a somewhat different angle. The object is to stimulate still further the search for the human sources of tuberculous infection, for it is only by their recognition and eventual elimination that the disease will be finally overcome. While it is well known that actively tuberculous patients are a present source of danger, it would help to emphasize the importance of the problem if those who, while clinically in perfect health, still cough up tubercle bacilli, either continuously or at intervals, were regarded as carriers of the disease from the point of view of the public health. Complete reliance on a negative radiograph may be misleading in some cases, and a more diligent search for tubercle bacilli in sputum would certainly yield valuable results.

Four cases are reported in which not the least sign of active tuberculosis was shown, but in which the patients were infectious from time to time.

The cases are discussed from the point of view of their danger to the public health.

As already announced, the Central Midwives Board for England and Wales has re-elected its chairman, Sir Comyns Berkeley. At the April meeting a letter was received from the Midwives' Institute stating that Miss A. A. I. Pollard felt unable to continue as a member of the Board after twenty years' service and that Miss C. K. Knott had been appointed in her place. The remaining members of the Board have been re-appointed. A resolution was passed by the Board expressing great regret at Miss Pollard's retirement and stating that she had devoted herself ungrudgingly to the service of the C.M.B. and of midwives for the past twenty years; in her the midwives of the country have had a representative who justly earned their affection and gratitude. "In championing the cause of midwives and of maternity and child welfare Miss Pollard has been aided by her wide and intimate knowledge of the midwifery profession and has been guided by her high regard for the dignity and responsibilities of that profession. Her enthusiasm for improvement has been tempered with wisdom and a shrewd appreciation of what was capable of early achievement. In all her dealings with her colleagues on the Board and with members of the profession she has displayed kindliness, sympathy, and a noble honesty of mind and purpose. It is a source of gratification to the Board that Miss Pollard has already seen success crown many of the movements she supported."

PELVIC ABSCESSES: DIAGNOSIS AND TREATMENT

BY

HAROLD DODD, Ch.M., F.R.C.S.

Surgeon to King George Hospital, Ilford; Assistant Surgeon to London Homoeopathic Hospital

There are few operations more satisfying to patient and surgeon alike than that of draining a pelvic abscess through the rectum. Collections of pus in the pouch of Douglas in the female and in the recto-vesical pouch in the male occur after any septic abdominal operation, but especially after a perforated appendix; less often they follow a perforated peptic ulcer, salpingitis, or suppurative diverticulitis. In a general surgical practice I meet about four cases a year; three will be caused by suppurative appendicitis with peritonitis, whilst the fourth will follow something less common. A recent instance developed after a partial gastrectomy for a huge gastric ulcer which was resected from the pancreas. An undetected pelvic abscess is one reason for a septic peritonitis not responding to sulphapyridine.

Diagnosis

The diagnosis of a pelvic abscess is straightforward. It is based mainly on the physical signs, for the symptoms as such seldom direct attention to the rectum. The story is approximately as follows:

After an abdominal operation the chart shows a raised pulse and temperature for about a week, then after two or three days of normal readings there is a return of the elevated pulse and of pyrexia to around 100° F. with a tendency to swing. The respirations throughout are unaffected, which negatives the possibility of a subphrenic abscess or respiratory sepsis. In a few days frequency of the bowels is noticed—perhaps four to six times a day. This is regarded as satisfactory at first, for it has often been preceded by constipation. Less often the bowels remain inactive. The stools consist mainly of mucus and a little fluid faeces. The patient is toxic, with colour pale or slightly grey, and the initial progress is obviously slowed down. The hand will be found coolish, the nails white instead of pink, and the pulse is small. The tongue is moist, smooth or shiny, and bright red, and the papillae have been shed: there is an exfoliative glossitis. It is interesting to watch this tongue condition recover when the pus has been drained: the whole of it may be affected, or occasionally only the tip or sides.

The abdomen is inclined to be tight, and to be full in the lower half, and the respiratory excursion is absent or even reversed—i.e., it is indrawn on inspiration instead of moving outwards. There is seldom abdominal tenderness or rigidity. In a thin patient visible peristalsis may be observed, raising the possibility of subacute intestinal obstruction; rarely a patient vomits, further strengthening this suspicion, but if there is the possibility of "pus somewhere" it must be sought out before considering intestinal obstruction, apart from an inflammatory paralysis of the bowel.

The diagnosis is clinched by inserting a finger into the rectum. According to the stage of development of the pelvic abscess when the examination is made, one of three states will be found. They are:

1. *The Early and Suspect Stage.*—The rectum will be found empty, dilated, and warm, and the mucous membrane is smoother than usual. The rectal wall at the tip of the finger is hard and unyielding, with induration. There is no fluctuation, and the impression formed is that the rectum is "set in felt."

2. *The Abscess Declared.*—A day or two later than the above, the findings will be the same except for a significant addition: at the tip of the finger, on the anterior wall, a dimpling spot will be discernible. This is the first sign of the rectal wall softening and the abscess pointing through it. The sensation to the pulp of the finger is almost identical with that experienced on palpating the tip of the nose—i.e., there is a soft spot between the two cartilages. It will be remembered that the reflection of the peritoneum is fully a finger's length away from the anus, so that in the early stages it is necessary to press up firmly to reach high enough, and that the finger will have to pass round the first fold of mucous membrane in the rectal wall; thus the examination is a painful one for the patient. I prefer to make it with the subject in the Fowler position and the knees wide apart. The dimpling spot having been detected, the time for operation has arrived, and this is the place through which to drain the abscess.

3. *The Abscess Obvious.*—The further development is when the rectal mucous membrane becomes oedematous and hot, the first valve of the rectum is obliterated, and there is an obvious bulging protrusion into the lumen. The tense bulge is so definite that fluid pointing into the bowel is undoubted.

The Abscess Ruptures.—A fourth stage, which should rarely occur, is that of a spontaneous evacuation of pus into the rectum, and this is passed into the bed-pan as a fluid stool. The abscess should be detected clinically before this.

An "Unusual" Presentation.—When the abscess points into the rectum from the peritoneal cavity it must traverse the pelvic cellular tissue. This usually becomes so indurated that spread along this plane is automatically limited. Rarely, however, in a debilitated patient the localization is not complete, and pus may break outwards and downwards through the sacro-sciatic foramen and point as an abscess on either buttock. The process is a quick one, and constant vigilance should be maintained to detect such a collection in a patient who is not progressing and who obviously has "pus somewhere." Another possibility is the abscess pointing in the groin at the pubic spine, having tracked along the round ligament or the vas deferens.

Vaginal Abscesses.—Pelvic abscesses also discharge through the vaginal fornices, but are rare in my experience, having seen only two in eighteen years of general surgical practice.

Opening a Pelvic Abscess

It is inadvisable to attempt the operation in bed. The patient is taken to the theatre and placed in the lithotomy position. The buttocks are elevated on a sandbag and protrude over the end of the operating table. This position is carefully arranged before the anaesthetic is given. Some surgeons perform the operation without an anaesthetic, with the patient in the knee-elbow position. Since the patient is already weak and toxic, as little anaesthetic as possible is given. A whiff of gas-and-oxygen or 3 to 6 c.cm. of 5% pentothal intravenously meets the need adequately.

The Operation.—The anus is dilated to admit two fingers, using plenty of lubricant. Tearing of the mucous membrane must be avoided: such fissures would be infected. A Sims duckbill speculum is inserted into the rectum, and the lumen is thoroughly cleansed of faeces and wiped out with antiseptic swabs. The dimpling or fluctuating spot on the anterior wall is located with the tip of the left index finger, and with this as a guide a long wide-bore needle attached to a 20-c.cm. syringe is confidently thrust through the suspicious area in the rectal wall. A hesitant penetration will fail to enter the abscess cavity. Aspiration will reveal the pus. If pus is not found, carefully check that the needle has been inserted through the softening place and that it has really penetrated the rectal wall. If no pus appears then the operation is not proceeded with, and observation on alternate days is maintained. When pus is found the syringe and needle are carefully held in position. A pair of uterine dressing forceps whose points are grooved on the inside are slid along the needle through the rectal wall and into the abscess cavity. Pus immediately emerges, often surprisingly fetid and in large quantities. As the flow shows, the syringe and needles are withdrawn and the forceps blades are opened in a north-and-south and then an east-and-west direction, thus making the opening in the rectal wall generous. In the early cases I used a large pair of Mayo scissors to open these abscesses. In one case a haemorrhage began which exsanguinated the patient and made a second operation necessary two hours later, followed by transfusion. It was surmised that the rectal wall, with a large vessel, was cut during the process of closing the scissors whilst turning them from north and south to east and west. Since then the uterine dressing forceps have always been used. They are more suitable, and no complication has been encountered.

The Drainage Tube.—The drainage tube is inserted through the anus and into the opening in the rectal wall; a stitch through the perianal skin anchors it for forty-eight hours, when it is removed and not replaced. A compress of perchloride of mercury 1 in 1,000 is applied externally and changed morning and evening.

After-treatment and Progress

The after-treatment is simple. The patient is nursed in the full Fowler position. On the day of operation only water is given, by mouth; the next day fruit drinks; citrated milk is added the day afterwards, and full milk and all fluids after this. At least six pints must be taken daily. So often a fluid diet is synonymous with starvation, and it is important to feed these patients adequately. The diet is steadily built up through semi-solids to one of fish and chicken.

The subsidence of the pulse, temperature, fullness of the abdomen, and general malaise is prompt and progressive. In only one patient have I seen a failure of resolution, when a pelvic collection of pus required draining three times. On each occasion the temperature and pulse fell for five or six days and then began to swing again.

No deaths have been seen after a drained pelvic abscess, but missed ones have been found at necropsy.

Summary

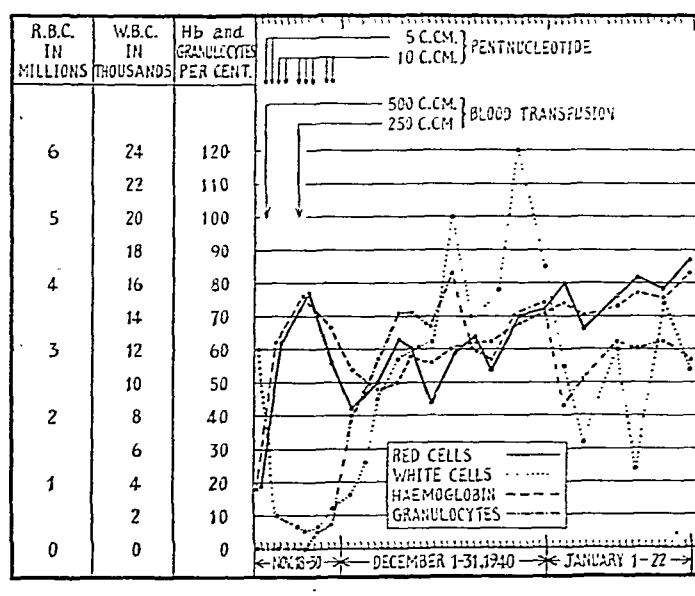
The clinical picture and treatment of intraperitoneal pelvic abscess following abdominal operations are detailed. A specially modified pair of uterine dressing forceps for opening the abscess are described. All instruments used in the operation must be long-handled, for the procedure is conducted through a narrow opening of some depth.

The annual general meeting of the Governors of the Imperial Cancer Research Fund was held at the Royal College of Surgeons on April 16, with Prof. H. R. Dean, Vice-Chairman of the Council, in the chair. The thirty-eighth annual report of the Fund was approved. [The report was summarized in the *Journal* of April 26, p. 639.] The Rt. Hon. Viscount Halifax was re-elected President for the year 1941–2, and Sir Holburt Waring, Bt., was re-elected Honorary Treasurer. Sir Cuthbert Wallace, Bt., was elected a member of the Council as a representative of the Board of Governors. The meeting passed a resolution of regret at the resignation of Sir Humphry Rolleston, Bt., who had been Chairman of the Council since 1924; he is now a Vice-President of the Fund.

A CASE OF AGRANULOCYTOSIS IN AN INFANT: RECOVERY

BY

H. CECIL BARLOW, M.B., L.R.C.P., M.R.C.S.



Honorary Physician, Lincoln County Hospital

The following case appears to warrant record because of its severity and the part played by blood transfusion and pentnucleotide in recovery.

Case Report

A girl aged 1 year and 11 months was admitted to hospital on November 16, 1940, obviously very ill. Dr. J. S. Topping, her doctor, gives the following account of her illness.

She was seen first on October 25, 1940. She was pale, seemed ill, and would not put any weight on the left leg; she appeared to have pain in the left knee. She was put to bed, the left leg was wrapped in wool, and she was given 7½ grains of sodium salicylate with 15 grains of sodium bicarbonate every four hours. On October 28 the temperature was 100° and the pulse 90, and she seemed better. Up to November 1 the temperature and pulse remained the same, but the leg was better and she could stand on it. On November 4 she began to have bouts of crying and kept putting her hand to her right ear; there was some congestion of the fauces and the right ear-drum was inflamed. The temperature was 101° and the pulse 100. For the next few days the bouts continued, and she was seen by an aural surgeon, Mr. J. J. Rainforth, who reported that there was no evidence of mastoiditis and advised sulphapyridine (M & B 693). During the whole of this part of the illness no other physical signs of disease were observed; in particular there was no enlargement of glands nor was the spleen to be felt. On November 11 she was given 0.125 gramme of sulphapyridine twice a day, and this was continued for five days, making a total of 1¼ grammes. The ear symptoms ceased, but she seemed so ill that she was sent to hospital.

On admission she was profoundly anaemic. Examination of the blood showed only 930,000 red cells per c.mm., and the haemoglobin was down to 18%. White cells were 12,000 per c.mm., with a differential count showing 5% large lymphocytes, 2% lymphoblasts, 93% small lymphocytes; no granulocytes could be found. She was poorly nourished, but apart from the extreme anaemia there was no evidence of disease in any organs. There was no ulceration of the mouth, fauces, or tonsils; neither the spleen nor the glands were enlarged, nor were they ever found to be enlarged during the whole course of her illness. The temperature for the first four days after admission ranged between 101° and normal; after then it ranged between 103° and 100° from November 20 to December 3, when it subsided by lysis and was normal on December 9. There was no obvious cause for the fever except the septic condition in the arms, at the sites of the blood transfusions. At one time there was a little bronchitis. The pulse ranged between 135 and 155.

On November 19 the patient received a transfusion of 500 c.cm. of citrated blood by the drip method and an intramuscular injection of 5 c.cm. of pentnucleotide. Her general condition improved immensely almost at once, but no granulocytes were to be found in the blood. The pentnucleotide was given twice a day for the following ten days and she had a further blood transfusion of 250 c.cm. on November 24.

The accompanying graph is a record of the blood picture from November 18, 1940, to January 22, 1941. It shows the rapid rise in the red cells and haemoglobin after the first blood transfusion. From November 18 to 25, after prolonged search, but not a single polymorph could be found in the blood films, although the pentnucleotide was being given regularly; and it was not until fourteen doses had been taken that any appeared, and then there was a rapid rise to 40%, fourteen days after the pentnucleotide had been begun. This rise steadily continued until a maximum of 83% was reached on December 17; after that there was a decline to normal. The number of white cells showed a remarkable fluctuation: from 12,000 on admission they fell rapidly to as low as 1,000 seven days later, after which they rose steadily to 12,000 by December 12; and, later, two counts of 20,000 and 24,000 were registered when sepsis was most marked in the transfusion wounds.

The general appearance of the child was remarkably improved after the first transfusion, but for a month she was listless and fretful, was difficult to feed, and showed a pronounced hypotonia. The sites of transfusion at the elbows became septic and sloughs appeared, and there was a complete agranulocytosis. The outlook seemed grave, but as soon as polymorphs began to be present the wounds became more healthy and slowly healed. A week after the second transfusion she became slightly jaundiced, but this cleared up in five days. In the beginning of January an indurated swelling appeared in the right buttock at the site of one of the injections of pentnucleotide; this was absorbed in ten days. During the last three weeks in hospital she steadily improved, and eventually could run about, took food well, and was happy and contented. A short course of light treatment seemed to help. She was discharged from hospital on February 1.

Commentary

At first the blood picture seemed to suggest an aleukaemic lymphatic leukaemia, but the progress of the case negatived any form of leukaemia. For several days, in spite of the most careful search, not a granulocyte could be found, and yet there were never any signs of throat infection. There is evidence that the child was anaemic before the sulphapyridine was given, and this condition, with a possible idiosyncrasy for the drug, may have so poisoned the marrow that it failed to produce any granulocytes. When the wounds at the elbows became septic it was feared that the infection would spread owing to lack of resistance. It was most noticeable how quickly the sores began to heal as soon as the polymorphs appeared. It is to be noted that after the transfusion the number of

ied cells and the percentage of haemoglobin greatly increased, but there was no improvement in the white cell count—rather the reverse. Another point to note is that the pentnucleotide was given for eight days before the polymorphs began to appear.

I am indebted to Mr. W. Chandler for the very careful blood counts.

Clinical Memoranda

Fatal Case of Burns Complicated by Gas Gangrene and Acute Duodenal Ulceration

The occurrence of two of the rarer complications of burns in the following case makes it worthy of note.

CASE RECORD

A man aged 60 incurred extensive third- and fourth-degree burns of the left leg and thigh owing to the scattering of the coals from his grate through a bomb explosion. The burns were cleansed under general anaesthesia, and tannic acid was applied. Two days later he was transferred to an emergency hospital. On the fourth day the general and local condition were satisfactory. At 11 a.m. on the fifth day gas and fluid were present in the calf of the leg. The pulse was 100 and the temperature 99°. One gramme of sulphapyridine (M & B 693) was injected intravenously. By 2 p.m., the time arranged for operation, the gas had spread to the mid-thigh. All muscle groups were invaded. A circular amputation 4 inches below the hip-joint was performed and the stump was covered with sulphanilamide powder. A further 1 gramme of sulphapyridine was injected intravenously. From the fifth to the eleventh day the patient was given 15 grammes of sulphapyridine orally and 5 grammes of prontosil album, the latter preparation being retained after the former had caused vomiting. 7.2 c.cm. of anti-gas-gangrene serum was also given. On the twelfth day his general condition was fair. The temperature was normal and the pulse 80. The stump was fairly clean, and there was no gas in the limb. Severe melaena developed on the sixteenth day and continued until his death nineteen days after the burns were incurred. Repeated blood transfusions had been given.

Swabs and a portion of muscle were examined on the day of operation. A film showed debris and Gram-positive bacilli. Anaerobic culture revealed large Gram-positive bacilli with subterminal spores and *B. pyocyaneus*, and demonstrated Gram-positive bacilli forming a stormy clot in milk—? *B. welchii*.

At necropsy an ulcer the size of a shilling was seen on the anterior wall of the first part of the duodenum. The second and third portions were moderately injected. There was old blood clot in the bowel. The stump was clean. There were no other pathological changes.

Microscopical examination revealed disintegrating mucosa. The surface epithelium had been shed, but glands were present in the submucosa. On the surface there was a suggestion of a serous exudate, with some round-celled infiltration. No evidence of fibrous tissue formation was observed, nor was there any other sign of chronic inflammation. The general appearances suggested some acute necrotic process.

This case and a similar one occurring previously have impressed upon me the importance of examining all cases of burns daily for gas infection. The rapidity of spread in the subcutaneous tissue—about eighteen inches in three hours—is remarkable. Whether the same rate of spread occurred in the muscles it is more difficult to assess.

JAMES MORONEY, M.B., Ch.B.,
Resident Surgical Officer to an Emergency Hospital.

Reviews

OFFICIAL HISTORY OF THE A.A.M.S.

The Australian Army Medical Services in the War of 1914–18. Vol. II. The Official History of the Australian Army Medical Service in the War 1914–18. The Western Front. By Colonel A. G. Butler, D.S.O., V.D., M.B., Ch.B. (Pp. 1,010; 212 illustrations, maps and graphs. 21s.) Canberra: Australian War Memorial. 1940.

The second volume of the story of the services of the A.A.M.C. in the last war is a worthy successor of the former one, which received our favourable comments. Colonel A. G. Butler, the editor, has taken a liberal view of his functions and has again given a fascinating story of the relation of the medical services to the fighting, this time on the Western Front, from the arrival of the Australians early in 1916, when the line had become fixed and trench warfare extended from the Belgian coast to the Swiss border, through the stage of attrition when heavy losses were suffered and a great number of casualties were caused by the attempts to batter the opposing lines, to the terminal war of movement, attack and counter-attack, which ended in the defeat of the German armies. The narrative chapters are followed by considerations of the special medical problems involved in each of these phases, and the administrative problems of the treatment and evacuation of lightly and severely wounded from France to the advanced base in the United Kingdom and ultimately to Australia. Changing problems required changed methods of tackling them, and high praise is given to the first Director of Australian Medical Services, Sir Neville Howse, and his staff for the way in which these problems were successfully solved. Details of surgical and medical treatment are naturally omitted, but a full discussion of the machinery of prevention of disease is given.

Colonel Butler is well qualified for the task he has carried through so successfully, because he saw service in the field as regimental medical officer, as commanding officer of a field ambulance, and as a member of the Corps staff. He has drawn his material from many sources, ranging from personal diaries and letters, written while the events described were shaping themselves, to the official medical histories of our allies and our enemies. The extracts made are apposite, illuminating the point under discussion, never redundant, and under the editor's skilled hand fitting aptly into the picture. It is interesting to trace the evolution of methods of evacuating the wounded under varying conditions of fighting on the Western Front and as experience grew. In this connexion reference is made to the distinguished service of Major-General G. W. Barber, D.D.M.S., Australian Corps, and his standing orders for the A.A.M.C. under his command are set out in full in an appendix. A special problem was that Great Britain was really an advanced base, and full tribute is paid to the work of Colonel D. M. McWhae in organizing the A.I.F. depots in the United Kingdom and dealing with the ultimate return of sick and wounded men to Australia. Throughout the volume the name of Sir Neville Howse recurs constantly, and the last chapter deals with the personality, policy, and outlook of the D.M.S., A.I.F., who wielded such power in the Australian Medical Services. It is a shrewd and well-informed appreciation of a great Australian.

Colonel Butler has produced a treatise rather than a history, and is to be congratulated on a valuable contribution to medical war literature of interest to many outside Australia. The print is clear, the illustrations (photographs, maps, diagrams, and sketches) are well chosen and

well produced. There is a comprehensive index, personal and general, and cross-references and notes are full and well arranged.

TEACHING THE DEAF CHILD TO SPEAK

Speech Training for the Deaf Child. By Sylvian M. Martin. With a foreword by W. Kingdon Ward. (Pp. 114 Cloth, 5s.; paper, 3s. 6d.) London: George Allen and Unwin, Ltd.

The situation of the deaf child is one of grave handicap at any time, and difficulties of transport must increase this seriously in time of war, for the special schools and clinics are not numerous. It is important, too, that the teaching of the child should begin as soon as the deafness is recognized, and also that the child should be taught in the right way. *Speech Training for the Deaf Child*, by Sylvian M. Martin, is a guide for mothers or relatives who may have to undertake the task of teaching a deaf child to speak. In concise and clear writing it is explained how this should be done, how the initial difficulties can be overcome, and how the training can be developed. The patience required to make the first contact with the mind of the deaf child by means of speech is emphasized repeatedly, and the teacher is encouraged by the assurance that often the child is absorbing quietly under an appearance of indifference, until it suddenly shows interest and responds.

The book is in two parts, the first dealing with the training of the deaf-mute child, and the second with the slightly deaf child. The explanations and examples of how the training should proceed are most thorough, and if they could be put into practice would enable the parent to teach the child so that the power of clear and intelligible speech is acquired. Anyone who has seen the patience, enthusiasm, and understanding which the skilled and trained teacher brings to her task must feel some doubt whether the parent can accomplish very much from the directions on the printed page, excellent as they are. If, however, circumstances are such that it must be done that way this little book by Miss Martin is an excellent guide and would be difficult to improve.

MANAGEMENT OF FRACTURES

A Complete Outline of Fractures (including Fractures of the Skull): For Students and Practitioners. By J. Grant Bonnin, M.B., B.S., F.R.C.S., M.R.C.O.G. (Pp. 508; illustrated. 25s. net.) London: William Heinemann (Medical Books), Ltd. 1941.

Of late several comprehensive works on fractures have appeared, perhaps as a reaction to the importance of the subject at the present juncture. The book under review is an addition whose form and content may be considered to justify its entering the field. Mr. Bonnin has managed to include a consideration of the whole subject within some 500 pages of a compact volume. In addition there are two short chapters on dislocations. There is nothing original in his approach to the various problems involved in the subject, but he gives a clear statement of the most recent views in these sections in which progress or change can be recorded during the past five or ten years. The essentially practical nature of the subject is clearly recognized, and the illustrations are mostly useful and assist in the clarification of the text.

The chapter on plaster technique is excellent and contains some commonsense observations on the dangers of unpadded casts. The author has not been frightened by the specialization devoted nowadays to head injuries and has produced a chapter on the subject which should fully serve the surgeon dealing with casualties. Acute traumatic bone atrophy receives some notice, but the author gives little intimation of the appearance of the condition elsewhere than in the hand. Admittedly the pathology of this condition remains obscure, but it is by no means rare in the lower extremity and in isolated long bones. The prognosis in these areas is better than is suggested in the volume under review.

The least convincing section is that on compound fractures. The author does not define clearly the limit of skin excision desirable in the operative treatment of these cases. He advocates the use of a window in the plaster over the wound—a practice which has little support in most circles at the present time. Again, his enthusiasm for primary suture will not be shared by all surgeons. It is perhaps unfair to make these criticisms of a textbook: the subject of wound treatment looms so large at the present time, and individual opinions on the subject are so firmly held, that close conformity of opinion on the subject is hardly to be expected. The absence of a definite recommendation in regard to the use of the sulphonamide group of drugs in prophylaxis and a somewhat sketchy paragraph on gas gangrene are subject to the above observations.

There is a suggestion in the introduction that the book is mainly designed for the use of students. It will certainly serve them well, but it also offers a sound working guide to those surgeons who are now perhaps unexpectedly concerned with the treatment of injuries.

PRACTICAL DIETETICS

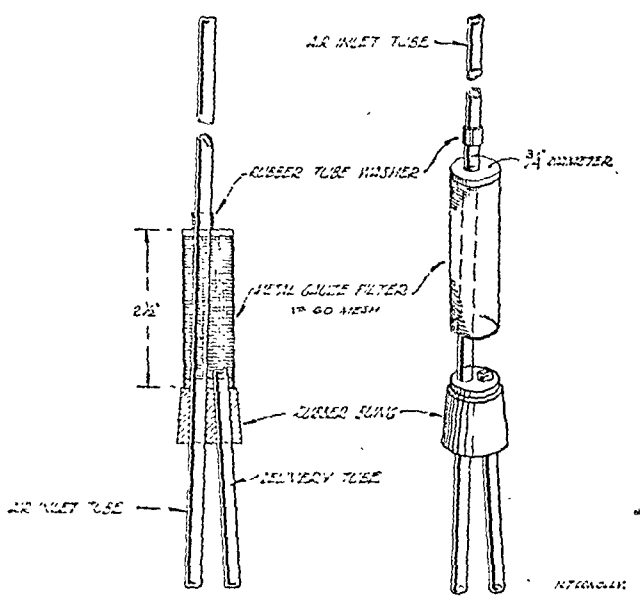
Dietetics Simplified. The Use of Foods in Health and Disease. By L. Jean Bogert, Ph.D. With Laboratory Section by Mame T. Porter, M.A. Second edition. (Pp. 742. 12s. 6d. net.) New York and London: The Macmillan Company. 1940.

The best way to review a book is to use it, and as one who has made considerable use of the first edition of Bogert and Porter the reviewer can say that it is an extremely useful and practical manual of dietetics. The second edition maintains the virtues of the first, among which we may enumerate attractive format and illustrations, adequate but not excessive physiological and clinical details, and clearly described diet schemes and recipes. Each chapter is followed by "Discussion Questions and Problems," and though the book has been planned for nurses and medical students, as well as others interested in dietetics, we cannot help feeling that the average graduate in medicine in this country would fail on these quizzes. And this, it seems to us, reflects not so much the high ideals of educative practice in the U.S.A. as the distortion of the British medical curriculum. A recent analysis of the bed costs in a provincial teaching hospital showed that nearly three times as much per patient was spent on provisions as on drugs and surgical materials. Yet, whereas the student receives extensive instruction in the action and prescription of drugs and the dressing of wounds and fractures, he receives practically none in dietetics. Every layman knows that drugs and operations are of little value in the chronic diseases which vex mankind, such as rheumatism, chest diseases, dyspepsia, and psychoneurosis, but though the medical profession pays lip service to such ideas as prophylaxis, physiotherapy, mental healing, and improved nutrition, no corresponding revolution has occurred in the curriculum. The average faculty of medicine acts on the belief that what was good enough for Astley Cooper, Bright, and Addison is good enough for to-day. It is difficult to see how this excessive conservatism can be overcome without strong pressure from without, but books on dietetics so attractively written and produced as Bogert and Porter cannot fail to exert an influence for improvement.

Notes on Books

Clinical Pellagra, by Prof. SEALE HARRIS of Alabama, is a work of collaboration in which ten other people have taken part. Prof. E. V. McCollum, in a brief foreword, describes it as a "philosophic treatment of clinical and experimental data of many kinds, contributed by many able workers who have contributed to the development of our knowledge of the biochemistry of nutrition and of the biologic agencies which act in conjunction with malnutritional states to undermine and pervert physiologic functions of certain types." It is not until Chapters 18 and 19 are reached that the editor-in-chief gives his description of the symptomatology and clinical manifestations of pellagra, and the general presentation lacks sequence. This book, of nearly 500 pages with many illustrations, is published by Henry Kimpton at 35s.

The Educational Advisory Board of the British Social Hygiene Council has issued a memorandum entitled "Human Biology and the Crisis in the Public Schools." It is obtainable from the British Social Hygiene Council, Tavistock House South, Tavistock Square, W.C.1.



Preparations and Appliances

A SIMPLE FILTER FOR PLASMA OR STORED BLOOD TRANSFUSION

Mr. Thomas C. J. O'CONNELL, M.D., M.Ch., assistant surgeon to St. Vincent's Hospital, Dublin, writes:

Various methods have been used in the filtration of stored blood or plasma before it is delivered into the patient's vein. The presence of fibrin will, under certain circumstances, lead to the formation of "clots," which take the form of either large masses or small flakes distributed throughout the medium. Filters used for the removal of these clots have been classified briefly as those situated (*a*) in the bottle containing the fluid; (*b*) outside the bottle.

The popular "gas mantle" filter has the obvious disadvantage that it must be renewed after each delivery. Types

SECTION THROUGH ASSEMBLED FILTER *FILTER PARTLY DISMANTLED*

of this filter have been placed both in the bottle and in the delivery "line." Glass beads have also been used for the purposes of filtration. When placed outside the bottle they must be enclosed in a special glass container. They present certain difficulties in cleaning, and are of course vulnerable. Metal filters outside the bottle have been employed with success, but they must be enclosed in glass containers—a method which leads to complexity of design. It is felt that filters situated in the delivery "line" cannot be entirely successful. When fibrin masses are relatively large they may block the outlet from the bottle. Shaking the bottle may dislodge them, but as often as not the entire delivery set must be removed and cleaned.

A filter placed within the receptacle itself would solve many of these difficulties. It is important, however, that such a filter should form part of the "giving set," be easily removed for cleaning, and be relatively cheap. It should, of course, stand up to all sterilizing processes, but should not corrode.

A filter on these lines has been devised by me. It is designed for use with the M.R.C. bottles which are to a great extent employed in blood or plasma storage. In principle, however, it may be used with any form of delivery set. It consists of a cylindrical metal filter, loosely fitted to the rubber bung and retained in place by the air-inlet tube, on which a small piece of rubber tubing is placed. It offers a large filtration surface, is easily removed and cleaned, and is relatively cheap and sturdy. The filter is made from copper gauze of size 60 mesh. This metal was found to be quite satisfactory, but stainless steel is preferable. The exigencies of war, however, prevent its use.

The diagrams illustrate the dimensions and fitting of the filter, which is supplied by Fannin and Co., Grafton Street, Dublin.

PERCALCIN

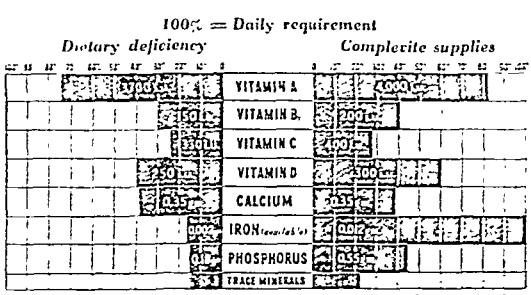
"Percalcin" (Evans Sons Lescher and Webb, Ltd.) is a solution of calcium in combination with mixed acids derived from glucose. The solution contains the equivalent of 1 gramme of calcium hydroxide in 25 c.cm. This is two and a half times as strong a calcium concentration as that contained in 10% calcium gluconate. Non-irritant solutions of calcium of this type suitable for intravenous or intramuscular administration are finding an increasing number of therapeutic uses. They are known to be of value in such conditions as tetany and urticaria. The vendors have prepared a pamphlet on the subject in which they suggest the use of percalcin in a wide variety of diseases.

IMMUNIZATION AGAINST ENTERIC FEVER AND TETANUS

We have received from Messrs. Burroughs Wellcome and Co. samples of two new products for active immunization against enteric fever. "T.P.3" is the designation given to a vaccine of the ordinary type containing 1,000 million *Bact. typhosum* and 750 million each of *Bact. paratyphosum* A, B, and C in each c.cm. Of the two recommended systems of administration, doses of 0.5 and 1 c.cm. are those adopted in the Army; the extra trouble involved in giving 0.1, 0.5, and 0.75 c.cm. with the same interval of seven to ten days between them is repaid by reactions of reduced severity. This product is available in rubber-capped phials containing 1.5 c.cm. (enough for the immunization of one person) as well as in 25 c.cm. bottles.

"T.A.B.T." is a mixture of T.A.B. vaccine (*Bact. paratyphosum* C being omitted from this preparation) and tetanus toxoid, made in two different proportions, each containing 1 c.cm. of tetanus toxoid, while one mixture also includes the bacterial content of 0.5 c.cm. of T.A.B. vaccine, and the second that of 1 c.cm. These mixtures are available either in single doses or in 25 c.cm. bottles. It is recommended that the two doses be given with an interval of not less than one month. The efficiency of immunization with tetanus toxoid is now fully accepted, and combination with T.A.B. vaccine has been found to increase it. The combined product causes no more reaction than the vaccine alone.

COATED AMMONIUM CHLORIDE TABLOIDS



Tabloid ammonium chloride (Burroughs Wellcome and Co.) has a special coating which is unaffected by the acid medium of the stomach but is broken down in the alkaline medium of the small intestine. Ammonium chloride is the most effective drug for reducing the alkaline reserve of the blood and increasing the acidity of the urine. It is a valuable adjuvant for various forms of therapy, such as the mercurial diuretics and many urinary antiseptics. The chief drawbacks to its use are its unpleasant taste and its irritant action on the stomach. The former effect can be avoided by giving sugar-coated tablets, but these do not prevent the latter effect. The specially coated tabloids reduce the local irritant effects to a minimum.

VITAMIN THERAPY

VITAMIN AND MINERAL DEFICIENCIES

Recent surveys have shown that there is widespread failure to obtain from present-day diet an adequate supply of the protective vitamins and minerals. Nevertheless, unless the physician has reason to suspect dietary deficiency, its manifestations are sometimes missed. But the results may very often be recognised by the presence of dental disease, which, in its turn, may be responsible for more far-reaching effects.

Complevite, the first *complete* vitamin and mineral supplement, has been produced expressly to compensate for the shortages which surveys have shown to be almost always multiple. The chart shows the optimal daily requirements, the average daily deficiencies in diets in the lower income levels and the amounts of the protective factors provided by Complevite.

* *The iron in Complevite exceeds the calculated deficiency expressly to combat the nutritional anæmia so common in children and in women of child-bearing age.*

Full particulars and complimentary bottle of tablets sent on request. Vitamins, Ltd. (Dept. B.C.N.), 23, Upper Mall, London, W.6.

VITAMIN B IN RELATION TO CERTAIN CONDITIONS OF THE SKIN

Healthy skin and mucous membranes are associated in the minds of most students of nutrition with a sufficiency of dietary vitamin A. It is less well known that certain vitamins of the B group are equally necessary and that their continued absence gives rise to well-marked lesions. The dermatitis and onychia of pellagra are well defined and clear up on the administration of nicotinic acid.

Deficiency of riboflavin causes a cheilosis which responds quickly to doses of this vitamin, and vitamin B_6 (adermin) is also known to be required.

Experience over many years shows that addition to the diet of a rich source of the B complex proves beneficial to the skin. The improvement is a gradual one and is particularly marked in the clearing of the troublesome lesions common in adolescence.

Bemax, which provides all the vitamins of the B complex, is recommended for improving the nutrition of the skin. The actual vitamin B analysis is as follows:

Vitamin B_1	10-15 I.U. per gm. (400 I.U. per oz.)
Vitamin B_2 (riboflavin) ..	0.9 mg. per oz.
P.P. factor (nicotinic acid)	1.1 mg. per oz.
Vitamin B_6 (adermin) ..	Richest source.

In addition to vitamin B, Bemax also contains vitamins A and E and assimilable iron. Clinical sample of Bemax and literature sent to medical men on application to Vitamins Ltd. (Dept. B.M.), 23, Upper Mall, London, W.6.

THE ADMINISTRATION OF VITAMIN E

WIDER SCOPE OF USES

While the main use of vitamin E up to the present has been the treatment of cases of habitual abortion and sterility of dietary origin (with success in about 70 per cent. of cases when whole oil—as in Fertilol—was given), wheat germ oil is now being increasingly used for cases of primary muscular dystrophy, amyotrophic lateral sclerosis, after poliomyelitis and in rarer cases such as amyotonia congenita.

The dosage of vitamin E which has proved effective in the treatment of progressive muscular dystrophy when administered as whole wheat germ (*Lancet*, 1940, 1, 10) is much smaller than that which has been reported as giving encouraging results when administered in the synthetic form (*Lancet*, 1940, 1, 431). It is possible that the other vitamins present in the natural product (Bemax) enhance the activity of vitamin E. This seems to be an argument in favour of the clinical use of vitamin E from natural sources, as in Fertilol and Bemax. Whole wheat germ oil has been available since 1934 as Fertilol, which is a highly active *natural* and stable source of vitamin E, plus the other naturally occurring factors of wheat germ oil. Complimentary box on request. *Vitamins Limited (Dept.* BFC.1), 23, *Upper Mall, London, W.6.*

Other Products of Vitamins Ltd.

PREGNAVITE Tablets *Vitamins A, B_1, C, D, and E with Calcium and Iron.* — To ensure an *adequate* supply of vitamins and minerals to meet the special requirements of pregnancy.

BEFORTISS (Brand) **Concentrated Vitamin B** — *Tablets.* 200 i.u. and 2 mg. per gm. For high dosage of the B complex. *Ampoules.* 2, 10 and 20 mg. For high Vitamin B_1 dosage.

TWO BRITISH PREPARATIONS FOR
LOCAL ANAESTHESIA

Introducing

FOR SURFACE ANAESTHESIA

'ANETHAINE' brand of butethanol is an extremely powerful surface anaesthetic. This substance, chemically allied to procaine, has hitherto only been produced abroad, but it is now manufactured by Glaxo Laboratories at Greenford.

A 1 per cent. solution of 'Anethaine' gives approximately the same effect as a 10 per cent. solution of cocaine. Therefore, although the **absolute** toxicity of 'Anethaine' is two or three times greater than that of cocaine, its toxicity **in the dilute solutions actually used** is much lower.

APPLICATIONS: Ophthalmology; oto-rhino-laryngology; urology. Anethaine produces effective surface anaesthesia for operative procedures on the eye, nose and throat, and for relief of painful conditions in accessible parts of the body covered with mucous membrane.

ANETHAINE

BRAND OF BUTETHANOL

Solution, 2 per cent. (coloured blue) in 25 cc. bottles; powder in 1 and 5 gm. bottles.

PRODUCTS OF THE GLAXO LABORATORIES

FOR INFILTRATION AND REGIONAL ANAESTHESIA

British preparations of procaine hydrochloride, and procaine hydrochloride with adrenaline, are now presented under the name

SEVICAINE BRAND

1 per cent. solution of procaine hydrochloride in boxes of 3×10 cc. ampoules; 2 per cent. in 15 cc. rubber-capped bottles; 2 per cent. with adrenaline (1 in 60,000) in boxes of 6 and 12×2 cc. ampoules and 15 cc. rubber-capped bottles.

THE WINTER EPIDEMICS

At the beginning of the past winter the public health authorities, as a consequence of the drastic changes in the social habits of the population following the intensive air raids, had serious forebodings as to the health of the community. It was feared that owing to the herd life lived by those who frequented shelters the incidence of infections might reach alarming proportions. Epidemic diseases, apart from their epidemicity, have a seasonal incidence. Their prevalence increases in the autumn, reaches a maximum in the early spring, and falls to a minimum in the late summer. It is common knowledge that there was no major prevalence of any specific infectious disease during the past winter, but it is of interest to review the general position in some detail. A table showing the incidence of some of the notifiable diseases in England and Wales during the winters of the past five years is included in the Epidemiological Notes for the week.

Anything approaching an exact comparison of influenza mortality with preceding years cannot be made yet, as the death records available relate only to the large towns, and the population of these areas has been seriously disturbed by evacuation, especially in the larger cities. Greater London accounted for two-fifths of the total population of the 126 large towns in peacetime. There were 2,217 deaths registered from influenza in the great towns during the first quarter of 1941. This was less than one-third of the total registered in the corresponding period of 1937 and about one-fifth of that in 1933, years in which influenza was very prevalent. Even if the figures for the large towns in 1941 give a gross understatement of the true position, it is evident, without being able to specify the exact size of the epidemic, that influenza mortality has not differed much from that of peacetime and is certainly below the level of some recent outbreaks. In the past winter the number of cases of pneumonia notified was slightly less than in the preceding winter and decidedly below the average of the triennium before the war. The notifications of enteric fever were greater than in the preceding period, but below the average for the winters of 1936–9. Dysentery also showed an increased incidence; nearly three times more cases were recorded in the past half-year than in the first winter of war, but the total was below the average of the pre-war triennium. Notifications of dysentery during recent months showed that there have been fairly severe localized outbreaks in widely separated areas. The number of notifications of cerebrospinal fever, 6,138, was nine times greater than the average for the immediate pre-war period, and although it was 706 above the number reported in the preceding winter the epidemic was not so severe. The increased incidence was due to the disease remaining at a much higher endemic level after the outbreak in the beginning of 1940 than before it; in the last quarter of 1940 there were 1,806 cases reported, as compared with 339 in the last quarter of 1939. The maximum weekly notifications were 406 in 1941 and 603 in 1940, while for the preceding four years no weekly total exceeded 50.

Of the common infectious diseases of childhood, more cases of both scarlet fever and diphtheria have been reported than in the preceding winter, when the incidence of these diseases was very low. The notifications of scarlet fever were only three-quarters of the average for the three winters immediately preceding the war, while the incidence of diphtheria was 90%. These diseases have not displayed an epidemic peak but rather a fluctuating seasonal rise. With regard to measles and whooping-cough, these diseases were not generally notifiable until November, 1939, so that it would be necessary to use the mortality rates for making a comparison over a series of years, and these are available only for the large towns. For purposes of comparison, the objection raised in the case of influenza to the use of the deaths for these areas would be more serious in the case of diseases of childhood, as the transference of children from large cities to areas with a low density figure was the principal feature of the evacuation scheme. The number of cases of whooping-cough, 44,160, reported in the first quarter of 1941 was six times that in the corresponding period of 1940, and the incidence has shown a distinct rise in the last few weeks. This increase is in agreement with the trend of the mortality curve of peacetime, which displayed a maximum in the beginning of the second quarter. This peak was absent from the 1940 returns. Notifications of measles numbered 204,158 in the first quarter of 1941 and were four times those recorded in the same period of 1940. The recent trend of the measles curve has been of interest, the most striking feature being the failure of the biennial epidemic, expected in 1940, to appear. The obvious explanation—the evacuation of children to country areas—may not be the correct one, because, judging from the mortality, the usual high spring peak was absent in 1939. The trend of the curve of measles mortality was practically horizontal between the thirtieth week of 1938 and the thirtieth week of 1940.

Despite the herding together of large numbers of the population in air-raid shelters the epidemics of the past winter have been, on the whole, below the average. The rather unsatisfactory position of dysentery and the large increase in cerebrospinal fever were not due to conditions arising out of air raids. In the large towns the effects of the new conditions of life upon the incidence of the common nasopharyngeal infections, colds, chills, etc., can only be a matter of conjecture, as no data are available on this point.

ATTACK ON RHEUMATISM

Planning for a better world is popular at the present time, and is one of the most striking signs of the confidence felt by the nation in the ultimate outcome of the war. No dreams of aggrandizement are entertained, but a determination that the world shall be made a better place to live in. While there may be differences of opinion as to how this should be brought about, few will disagree that one of the first steps must be to build on the ruins created by the air-raids better houses in better surroundings, and in this and kindred ways to raise the standard of living and lessen the incidence of disease. With this aim in view, although the idea had its birth in pre-war days, Lord Horder, as chairman of the Empire Rheumatism Council, has drawn up a "Plan for National Action"[1] to deal with rheumatic diseases. The various forms of rheumatism present one of the most important unsolved medical problems in the community. The economic damage resulting from them is estimated to exceed £25,000,000 a year in England and Wales, while the toll of pain and disablement is enormous. The American Committee for the Control of Rheumatism in its *Primer on Rheumatism* (1934) stated: "Chronic arthritis is generally recognized in all European and North American countries as the most important problem that chronic disease presents. . . . A careful house-to-house survey in the State of Massachusetts has shown that there are more cases of chronic rheumatism to-day than of heart disease, tuberculosis, and cancer combined."

Some education authorities, notably the London County Council, have done important work and achieved striking results in dealing with rheumatism in children. The School Rheumatism Supervisory Scheme of the L.C.C. is probably the best of such existing organizations. But the figures already quoted refer to chronic rheumatism in adults. Little has been done to provide systematic treatment and, what is of equal importance, to instruct adults in the best preventive measures to take against rheumatic disease. The nature of specific infection in acute rheumatism has yet to be demonstrated, though important work is being carried out by one of the Research Fellows of the Empire Rheumatism Council and by other investigators. While there is much evidence that bacterial infection is important in rheumatoid arthritis, it is certain that there are other aetiological factors of equal or perhaps greater significance. Such factors are briefly discussed in the booklet describing Lord Horder's plan: heredity, occupation, diet, climate, housing conditions, and psychical influences are all of importance, and nerve strain must not be overlooked. It is to be seen whether the dietetic restrictions imposed by the war will in the long run be harmful or beneficial; but it is more than likely that as a result of war conditions rheumatism will be more prevalent, not only among troops exposed to the conditions of active service, but also among civilians as a result of shelter life, ruined homes, strenuous work in munition factories, warden duty, fire watching, and so on. In any case, a preventive campaign must stress the part which these various factors may play in aggravating the disease.

Lord Horder touches on these preventive measures, but his main purpose is curative: "to note the existing facilities for treatment and to suggest how they can be extended." The principal methods at present in vogue are critically considered, and it is concluded that some are likely to be used only in a small percentage of cases and that a national plan of treatment would at first provide only for those methods which are likely to be of service in the majority of cases. The principle suggested is the concentration, at a few appropriate centres, of specialist knowledge and equipment, with subsidiary centres grouped around them but situated in populous places. The specialized rheumatism treatment centres would use as a nucleus existing institutions such as the spa hospitals, the Red Cross and other clinics, and such general hospitals as have established special rheumatism departments. The function of these specialized centres would be to provide postgraduate training and to carry out research in its widest sense. They would have beds for the treatment of serious cases referred from the subsidiary centres, whose duty would be to provide material for clinical research and teaching. Although not specified in the "Plan," it would be an advantage to provide instruction for fifth-year students, because those who go into general practice will find rheumatic diseases responsible for a large proportion of their daily work.

The local treatment centres would work on the lines of an out-patient department. Equipment for the most useful forms of physical treatment would be required on an adequate scale. A staff of trained masseurs and of special service workers would also be needed. Their task would be to see that simple home treatment was properly carried out and to remedy so far as possible faulty conditions of living. The directors of the local centres would devote their whole time to the work and should have been specially trained for it. It would fall to their lot to determine how far the subjective symptoms not infrequently put forward by the "work-shy" were justified. The scheme should so far as possible allow the general practitioner to make use of the facilities available at the centre. Under present conditions physical measures, which are generally admitted to be of the first importance in the treatment of rheumatism, are available for very few. For juvenile rheumatism the existing machinery for maternity and child welfare could be readily expanded to include the resources of the special centres and to make these available for those who cannot be treated and supervised at home. But for rheumatism in the adult new machinery and equipment would in most places have to be established.

Already child welfare and ante-natal clinics, and in many districts the out-patient departments of the large general hospitals, have encroached on private practice, and it is clear that Lord Horder's scheme would, unless very carefully organized, make still another inroad. As already suggested, however, it should not be impossible to devise a scheme which would enable the patient's home doctor to participate in the treatment of his patients. He would in this way gain knowledge of the greatest value to him in his daily work. The "Plan" deserves careful study by all concerned.

METHODS OF AIR DISINFECTION

It will not have escaped the notice of any assiduous reader that since the war began strenuous attempts have been made by several groups of workers to perfect a method for disinfecting closed atmospheres chemically. Had any such method been in general use in air-raid shelters and elsewhere during the past winter, the incautious observer might have been tempted to attribute to it the low incidence of cerebrospinal fever, influenza, and pneumonia under conditions which were expected to produce severe epidemics. This is not to imply that the disinfection of air may not be a valuable safeguard when air-borne epidemics have in fact begun, and in the breathing space which summer conditions should afford it will be well to take stock of progress in this matter. It is perhaps not generally understood that no fewer than five distinct methods of disinfecting air have been proposed. Ultra-violet light so applied as to be efficient requires an installation of prohibitive cost for large-scale use, and as it is almost without effect on bacteria in dust particles filtration is also necessary. Smokes are advocated by C. C. Twort and A. H. Baker,[1] who arrived at their present conclusions by way of experiments to determine whether tobacco smoke would interfere with the action of disinfectants suspended in the air; this it did, and the smoke itself had no disinfecting action, in spite of popular belief to the contrary, but smoke from smouldering cardboard or incense was unexpectedly found to be highly bactericidal. They dryly remark that "the practice of burning incense during religious ceremonial has a rational basis," as if the priests of some three thousand years ago who introduced this practice were directed by the same instinct in matters of hygiene as seems to have inspired many injunctions in Leviticus and Deuteronomy. The three methods which on present evidence appear to have a more serious claim to attention all consist in projecting a spray of disinfectant solution in the form of fine droplets; the differences between them lie not so much in the nature of the solution used as in the behaviour of the droplets so formed. According to A. H. Dodd,[2] who does not specify the material to be used but may be understood to refer to an emulsified disinfectant of coal-tar origin, spraying of a dilute solution should be continued until the evaporation of finer droplets has saturated the atmosphere with water vapour; condensation then takes place on any solid particles containing bacteria, which are carried to the ground, where disinfection is completed in a fluid film also produced by the spraying. This proceeding, assuming that it can be made to act in this way, has the merit of dealing also with floor dust. The "aerosol" theory, on the other hand, postulates contact between minute droplets of disinfectant solution and bacteria or infected solid particles; this takes place in suspension in the air, and to achieve it the qualities demanded of the disinfectant droplet are small size and persistence; the latter quality has been attained by the use of glycerin or other non-evaporating solvents. It seems clear from the work of C. C. Twort and his colleagues[3] and C. H. Andrewes and others[4] that certain phenolic disinfectants used in this way are highly efficient: the best according to Andrewes is a solution of hexyl-resorcinol in propylene glycol, but these two substances are not at present available in adequate amounts for large-scale use. He accordingly recommends the use of a sodium hypochlorite solution, which is readily manufactured in unlimited quantities, is efficient, harmless, and almost odourless, and is itself a deodorant. This is the method which has been consistently advocated by A. T. Masterman,[5] who has now published a spirited rejoinder to the paper of A. H. Baker, S. R. Finn, and C. C. Twort,[6] in which they cast doubts on the efficiency and practicability of aerial disinfection by means of hypochlorite solutions. Their mistakes, according to Masterman, include not only technical imperfections such as the employment of inefficient atomizers, but the assumption that the "aerosol" theory is applicable to this method. He describes observations which show that minute droplets of a hypochlorite solution evaporate with extreme rapidity, and the product, owing to interaction with atmospheric carbon dioxide, is hypochlorous acid gas. This, then, is a third and totally distinct effect of spraying—the formation of a bactericidal gas. The advocates of these different methods stand at the three points of a controversial triangle of no small interest, and it would be premature to pass judgment on the differences between them. It may confidently be said, however, that the hypochlorite method has more experimental work behind it than any other: phenolic disinfectants acting as aerosols are efficient but expensive or in short supply, while the idea of washing bacteria out of the air and killing them on the ground at present lacks the support of adequate experimental data.

DANGERS OF POSTERIOR PITUITARY EXTRACT IN LABOUR

A drug whose power was not fully appreciated became available when the action of extracts of the posterior lobe of the pituitary on uterine muscle was discovered. There were many who heralded the discovery as marking a new era in obstetrics, and in some clinics the available preparations were spoken of as being "physiological forceps." The physiologist has shown that the uterine response to pituitary stimulation is not so simple as was at first thought, and over twenty-five years of clinical experience have revealed dangers which were unsuspected. The use of pituitary extracts in labour was reviewed recently at the ninety-first Annual Session of the American Medical Association in New York, when papers were read before the Section of Obstetrics and Gynaecology by Drs. Sharkey, Pendleton, and DeLee.[7] In spite of the wide use of the hormone during the first and second stages of labour—a practice which was deplored by all three speakers—it is to be noted that in the discussion following the papers no speaker rose to defend this. DeLee referred to the increasing demand among American women for "streamlined labour," and stated characteristically that such a labour could be as safe as a streamlined parachute. Reynolds has shown that posterior pituitary preparations produce tetanic contractions of the uterus, and stress was laid on the dangers to the mother and the foetus when this happens during labour. Cerebral damage with stillbirth and neonatal death, maternal lacerations, uterine rupture, and damage to the pelvic floor with resultant prolapse are the most common complications. DeLee stated that the number of cases of uterine rupture due to the administration of pituitary extract would never be known, for either the cases were not reported or the patient was buried and the death recorded as being due to shock, haemorrhage, or embolism. Attention was drawn to the important fact that even doses as small as 3 minims (0.2 c.cm.) can be dangerous to the mother and the child, and it was claimed that there was no evidence to suggest that compound preparations such as thymophysin are any safer than

[7] *J. Amer. med. Ass.*, 1940, 115, 1315, 1318, 1320.

pituitrin or pitocin. In an analysis of the records of St. Vincent's Hospital, Kansas City, Dr. Pendleton found that when pituitary preparations were given during labour operative intervention was increased and the stillbirth and neonatal death rates were more than doubled. The speakers agreed that the use of pituitary preparations during labour placed a grave responsibility on the obstetrician, a responsibility which he is wise to avoid. While remembering the dangers associated with the abuse of these preparations, it is well to acknowledge the service they can safely render when employed with care. Pituitrin helps the uterus to expel its contents during the process of abortion, and in those cases in which evacuation of the uterus is necessary an initial injection of pituitrin into the cervix reduces haemorrhage to a minimum and greatly lessens the risk of perforation. Pituitrin is also of value in the induction of labour; but should be administered in small doses—for example, 0.25 c.cm.—which may be repeated at half-hourly intervals but must be discontinued if pains begin. It must not be given if a placenta praevia is suspected. During labour the hormone should not be used, and in a prolonged second stage an episiotomy or an instrumental delivery is safer than the "physiological forceps." In post-partum haemorrhage the drug is most valuable but has no advantage over ergometrine, and has the great disadvantage that on rare occasions it gives rise to severe shock.

INDIAN HEMP

The hemp drugs are derived from the resinous extract of the female flowers of the hemp plant, *Cannabis sativa*. Cannabis has for long been one of the paradoxes of pharmacology. Under a host of names, such as charas, hashish, bhang, ganja, marihuana, and Mary Jane, it is widely used as a drug of addiction, and there are many vivid descriptions of its action. Nevertheless, except for its use as a colouring agent in corn paints, it has never firmly established itself in human therapeutics; it has been removed from the *British Pharmacopoeia*, though it is still widely used in veterinary medicine. The reason for this lies in the inconstancy and frequent inactivity of the drug. Two recent reviews of the chemistry and the pharmacology of the hemp drugs by Todd[1] and Macdonald[2] give good cause for believing that these defects will soon be remedied. The Egyptian, Indian, and American hemp plants differ slightly from one another. Within each species there is a great variation in the content of active material. The active constituent is contained in the high-boiling portion of the resin, is nitrogen-free, and can be distilled in a high vacuum without decomposition. The earlier investigators made the mistake of believing that this portion was homogeneous, which is far from being the case. Moreover, they were handicapped by unsatisfactory methods of assay. It is now known that the reaction (called the Beam test) in which a red-violet colour appears with alcoholic potassium hydroxide is not given by the active constituents of the drug. Biological tests are therefore used: *Cannabis indica* produces in dogs a characteristic ataxia, and in cats there is also abolition of the corneal reflex. A number of chemical principles have been isolated from the resin. Cannin, the most recently discovered, shows the typical action of the drug in dogs. Cannabinol, cannabidiol, and its isomer cannabol are practically inert. These substances are cryptophenols, apparently derived from the condensation of a terpene and a resorcinol derivative. Synthetic tetrahydro cannabinols, of which a variety has now been produced, show hashish activity: it is more than likely that one of these will replace the crude drug in future therapeutics. The most important applications will probably lie in the field of mental illness. Macdonald describes *Cannabis indica* as the best drug for depressive mental conditions. Not even opium gives the same feeling of well-being, both physical and psychical, and opium is also inferior to hemp because of its tendency to addiction, its depressant action on respiration, its tendency to constipate, and the frequency of "hang-over" next day. Moreover, the power of hemp to revive old memories and recall in detail things long forgotten may be a powerful aid to psychotherapy. Difficulties may arise from the facts that there is great individual variation in susceptibility and that the response in the same individual may vary greatly at different times. Nevertheless we shall look forward with interest to the application in man of these important advances in the chemistry and pharmacology of *Cannabis indica*.

FITNESS OF AIR PILOTS

It has long been recognized that only a small percentage, probably not more than 5, of air crashes are due to mechanical failure. It is not the aeroplane but its operation which is chiefly at fault. Ferree and Rand,[1] in a survey of the problem, stress the incongruity of maintaining an aeroplane in perfect condition and giving relatively little attention to the pilot. The fitness of the pilot is, of course, not a mechanical problem. There is, therefore, all the more reason for their recommendation that pilots should be frequently re-examined. The complexity of the problem makes it necessary to have tests of a number of different functions. The authors describe an instrument which should facilitate such tests. It should be possible with this instrument to gauge dynamic speed, capacity for night flying, reaction to changes in altitude, and susceptibility to ocular fatigue. The instrument is electrically operated, and it should be possible to carry out the examination in ten minutes. The problem is of importance; but Ferree and Rand appear to be speaking more of indifference to these questions in the United States than in this country, where the Medical Department of the Air Ministry has paid great attention to them from the time of its establishment. There is no reason to assume that the authorities here have either ignored or overlooked the fundamental difficulties stressed by the writers of this paper.

RHEUMATIC CEREBRAL DISEASE IN SCHIZOPHRENIA

There is something of the attitude of the defeatist in the willingness of many psychiatrists to accept the position that structural changes in the brains of schizophrenics cannot and never will be demonstrated. A paper describing a serious attempt to discover a structural basis for dementia praecox[2] therefore makes stimulating reading. Bruetsch found the post-mortem incidence of chronic rheumatic endocarditis in a series of cases of dementia praecox to be 9%. This is a high figure for a mental hospital population, as it does not include cases of acute rheumatism. The average incidence in general hospital populations, including acute cases, is considered to be well under 4%; and the incidence in a large American mental hospital (Indianapolis), including a high proportion of necropsies on cases of dementia praecox, was 5%. The basic fact, however, in Bruetsch's paper is not the apparent high incidence of chronic rheumatic endocard-

[1] *Brit. J. Ophthal.*, 1940, 24, 581.
[2] *Amer. J. Psychiat.*, 1940, 97, 276.

itis in schizophrenics, but the discovery that in all such cases there was diffuse rheumatic vascular disease of the small cerebral arteries. The histological evidence suggested that the infection was active and recurrent, and associated with the arterial lesions were areas of infarction and foci of neurogliosis. In all cases other possible factors such as cerebral arteriosclerosis and syphilis were absent. Bruetsch considers that the vascular and parenchymatous changes which he describes were as extensive as the cerebral damage seen in meningo-vascular syphilis and in cerebral arteriosclerosis accompanied by mental disease. He makes the claim that rheumatic cerebral vascular disease should be given a place in the aetiology of dementia praecox. This claim must be regarded seriously if it is accepted that dementia praecox, whilst being a clinical syndrome, is not an aetiological entity. Bruetsch discusses the relation of the cases to chorea. He notes that a history of chorea is always regarded on the basis of clinical experience as more than an incidental factor in the development of a psychosis, and suggests that if a rheumatic recrudescence involving the brain occurs in later years it may be that not chorea but mental symptoms will result. The paper records the results of a painstaking research and is well illustrated. The histological diagnostic criteria are based on the work of von Glahn and Pappenheimer,[1] Karsner and Bayless,[2] and Gross *et al.*[3] It is pointed out in conformity with the modern conception that rheumatic vascular disease may be widespread throughout the tissues, that lesions in the brain were first described by von Sántha in 1932.[4]

PITUITARY AND SENSITIVENESS TO INSULIN

For a number of years it has become increasingly clear that, although the majority of diabetics can be restored to a state approaching normal by appropriate diet and by injections of insulin, in a number of these the essential disorder is certainly not merely an inadequate production of their own insulin. Diabetics may be divided broadly into two groups according to their reactions to insulin. The first group—typically young diabetics prone to develop ketosis—is characterized by a response to insulin with a fall in blood sugar essentially similar to that of a normal person. It is possible that in this group failure of adequate secretion of insulin is the fundamental cause of their diabetes. In the second group a relative insensitivity to insulin is found, a dose of insulin causing little or no fall in blood sugar. To this group commonly belong the elderly diabetics in whom the disease runs a mild course with little tendency to ketosis. In members of this group insulin has not its normal power to facilitate the passage of sugar from the blood stream to the peripheral tissues. Some abnormality is apparently present which interferes with the action of insulin, and evidence gradually accumulates that this abnormality is in some way connected with the pituitary gland.

In many experimental animals a great increase in sensitivity to insulin results from removal of the pituitary gland. From the anterior lobe of the pituitary can be extracted Young's "glycotropic factor," and if this is injected into the hypophysectomized animals their sensitivity to insulin is much reduced. It seems, therefore, that in the normal animal the continued production of this factor prevents too great a fall in blood sugar after a dose of insulin. Injection of this glycotropic factor into normal animals leads, in a few hours, to a complete insensitivity to insulin, and yet the factor, when injected by itself, has no appreciable power to raise the blood sugar level. This glycotropic factor thus appears to act as a specific "anti-insulin," and as such is clearly likely to play an important part in the phenomena of diabetes, especially in that type which is relatively insensitive to insulin. Support for such a view was provided by de Wesselow and Griffiths,[1] who found that the serum of some diabetics, when injected into rabbits, diminished the animals' sensitivity to insulin in the same manner as does the glycotropic factor. Himsworth and Kerr[2] have recently been investigating the point. Having acquired experience in the detecting of glycotropic activity they applied this to a search for its presence in diabetic blood serum. Twenty-seven patients were examined, of whom twenty-two were of the insulin-insensitive type. In no case was any glycotropic activity found. They were, however, equally unable to demonstrate glycotropic activity in the serum of rabbits previously made insulin-insensitive by injection of the factor in large amounts. Their failure in the human subjects is therefore no proof that the glycotropic factor is not involved in this insulin-insensitivity. But the injected rabbits were found to excrete the glycotropic factor in their urine, and from this it could be concentrated by adsorption on benzoic acid. The urine of the human diabetics was then examined in the same manner, but this yielded no evidence of excretion of the glycotropic factor. The significance of this negative finding was greatly enhanced by the fact that the positive results were, in contrast, obtained with the urine of three cases of hyperpituitarism—one of acromegaly and two of Cushing's syndrome—which had sugar curves of diabetic type. But though no direct proof of the involvement of the glycotropic factor in insulin-insensitivity has thus been obtained, there nevertheless remains indirect evidence that some such mechanism exists. Himsworth[3] had shown that the sensitivity of a diabetic to insulin can be increased by a high carbohydrate diet or reduced by one low in carbohydrate. The same phenomenon can be observed in rabbits, and Himsworth and Scott[4] have demonstrated that this is dependent on an intact pituitary gland, since hypophysectomized rabbits, unlike normal ones, do not show reduced sensitivity to insulin when kept on a diet low in carbohydrate, whereas they do so if injected with the glycotropic extract of the pituitary. Thus although good evidence has been forthcoming that the pituitary is in some way responsible for some forms at least of insulin-insensitivity, the precise nature of its role still eludes clear demonstration. It is evident, however, that the discovery of insulin, important as it is from both theoretical and therapeutic standpoints, has still not revealed the actual cause of the diabetes it so effectively treats.

We record with pleasure that on April 24 Dr. G. C. Anderson, Secretary of the British Medical Association, and Dr. E. C. Morland, Editor of the *Lancet*, were elected Fellows of the Royal College of Physicians of London under By-law XXXIX (b), which enables the College to honour in this way those, not being Members, who have distinguished themselves in any branch of the science or practice of medicine.

We regret to announce the death of Mr. J. Hogarth Pringle, F.R.C.S., consulting surgeon to the Glasgow Royal Infirmary.

POST-WAR MEDICAL EDUCATION IN LONDON

WITH SPECIAL REFERENCE TO THE MUNICIPAL HOSPITALS

BY

SOMERVILLE HASTINGS, M.S., F.R.C.S.

The municipal hospitals of London have been so tucked away in back streets and obscure corners that few people realize that they contain in ordinary times thrice as many patients as the voluntary hospitals. It has long been felt that insufficient use has been made of the resources of these hospitals for teaching purposes. Accordingly it may not be without interest to state briefly what teaching has been done in them since the war began, and to make suggestions for their further use after the war. It is perhaps hardly necessary to point out that in anything I have to say I am expressing my own views only and in no way committing the London County Council, which is in control of the municipal hospitals of the County of London.

When I was a student we came in contact with the municipal hospitals in two directions only. On two afternoons a week for about two months we attended at one of the fever hospitals for lectures and demonstrations. We also occasionally visited a mental hospital for similar purposes. Most of us regarded these visits as pleasant interludes, but my chief recollection of them is in wondering what advantage was to be gained by the use of the much-soiled overalls at the fever hospital and how some of the apparently normal individuals at the mental hospital managed to find their way there.

To-day I learn that attendances have still to be made at fever and mental hospitals and that a good many students are no longer doing their midwifery "on the districts" as I did, but in municipal and other hospitals. From the medical point of view this is no doubt all to the good, but the sociological value of a month on "extern" must not be forgotten. In it the student, perhaps for the first time, comes into direct contact with poverty in all its nakedness and ugliness. Last summer before the "blitz" started each of twelve of the municipal hospitals of London was taking two to four medical students at a time from ten of the medical schools for midwifery training. In most cases the students attended the hospital for a fortnight only, but a good many remained three weeks or a month, and there is undoubtedly much to be said for this longer period of stay. With few exceptions the students lived in hospital, the Council making a charge of 30s. a week for board, lodging, and laundry. It is, in my opinion, important that the student should reside in hospital, as otherwise a good deal that is of interest and importance is certain to be missed. Since September last the number of confinements taking place in London has considerably decreased, and it has accordingly been found necessary to restrict the number of students in attendance.

Before the war a certain amount of undergraduate teaching was undertaken in L.C.C. hospitals, for the most part by teachers directly associated with the medical schools. On the declaration of war a large number of students were allocated to various municipal hospitals to act as casualty dressers under the Emergency Medical Scheme, and, although their services were not required to the extent that had been anticipated, many were glad to receive clinical instruction in the wards of these hospitals.

Clinical Teaching

The result of the war, so far as clinical teaching in the hospitals with medical schools is concerned, has been twofold: In the first place, the number of beds occupied by cases suitable for teaching has greatly decreased; secondly, the teaching staff have been dispersed and are in many cases either in the Services or working at hospitals remote from their medical schools. Accordingly a good many of the municipal hospitals of London were requested by those responsible for the medical schools to provide or increase their facilities for clinical teaching. Before the wanton destruction of hospitals began in September last, twenty-three municipal hospitals were receiving students from ten medical schools. In most hospitals medicine and surgery are taught, but where facilities are adequate gynaecology, pathology, and paediatrics are added, and in three anaesthetics and in one venereal diseases. The method of teaching varies. In some hospitals students act as clinical clerks in the wards; in others they attend daily or weekly rounds and demonstrations, or work in the operating theatres or receiving wards. In many instances they spend the morning in hospital and go to the medical schools for lectures or tuition in the afternoon. About half the students live in hospital: there is much to be said for this when accommodation is available, as so many emergencies have to be dealt with in the evening or at night.

The clinical teaching has in the past been undertaken (1) by the teaching staff of the medical school, who visit the Council hospital exclusively for this purpose; (2) by the consulting staff of the municipal hospital, who attend at regular times weekly (the position of these officers is slightly different from that of the consultant staff of a voluntary hospital, as they are not in charge of beds but for the most part act as true consultants: they give advice as to diagnosis or treatment of cases submitted to them, sometimes performing any operation required, sometimes the operation being done by the resident staff); and (3) by the staff of the municipal hospital, who are themselves responsible for the medical care of the cases used for teaching. In some hospitals one only of these three methods of teaching is adopted; in others two; and in three hospitals all methods are in use. Undoubtedly there is something to be said for each. The staff of the medical school should be experienced teachers and should know what their students require. On the other hand they are not in actual charge of the patients, and their position in the hospital is, to say the least, somewhat invidious. I do not think the point of view is often expressed, but I do know that some of the municipal hospital staff, who are themselves well qualified, keen on their work, and good teachers, do feel a little uncomfortable when someone from outside comes to give instruction on cases which they have carefully studied. The position of the consultant staff of the Council hospital is of course different, as they have in most cases seen the patients taught on in consultation with the resident staff, although they cannot be expected to know as much about them as those who see them every day. Other things being equal, therefore, I would suggest that the teaching is best carried out by the regular hospital staff.

And here it may be useful to inquire what is to be gained by the use of municipal hospital beds for teaching purposes. From the students' point of view it will be readily admitted that, since at least 50% of them will probably be entering general practice, an intimate knowledge of the ordinary affections, chronic as well as acute, is most essential. This is the very type of case which has to be admitted to the municipal hospitals, not so much because of medical interest or the need for special treatment, but because the patient cannot be looked after properly at home. Gastrectomies and oesophagectomies have to be undertaken, and the student may be fortunate enough to meet with two or three of each during the rest of his professional life; but it is patients with chronic bronchitis, rheumatism, and heart failure that will occupy most of his time.

Relations with the Student

From the point of view of the municipal hospital I would myself welcome the students whole-heartedly. There is nothing like teaching for consolidating one's knowledge and exposing one's ignorance, especially when the taught are keen critical young people at the zenith of their mental capacity. In my opinion the municipal hospitals have suffered in the past from too much isolation. It is good for all concerned to bring in people from outside, and not least perhaps for the nurses, who are usually glad to meet the students and have been known to

make lasting friendships with them. I have discussed the position of students with many medical superintendents and not a few resident physicians and surgeons, and, without one single exception, they have all told me they were glad to have them in hospital.

The relation between the municipal hospital and the student seems to vary a great deal. In some cases the student appears to drift in, take up residence, and remain for a varying time until he desires a change, without the smallest interest being taken by his medical school. In others the work is systematized. Until the East End hospitals were so much knocked about, seven were (and three still are) used by students of the London Hospital, where the policy of the Medical School is to retain its students during the first clinical year directly under the charge of its own hospital staff, and give them careful and detailed teaching on a relatively small number of selected cases: but during the second year, after instruction in pathology, fevers, mental disease, obstetrics and gynaecology, to send them to municipal hospitals, where the greatest variety of clinical experience can be found. Most of the students, I am informed, live in the hospitals to which they are attached. This is said to be very greatly to their educational advantage, for not only do they see emergency admissions during the night but they come to feel that they are part of the organization of the hospital, and in consequence profit and gain experience. During the last clinical year students are allocated to hospitals near the London Hospital or to the "London" itself. Many are living at the near-by municipal hospitals. Students at these hospitals are sufficiently near the "London" to come up several days a week in the afternoon to attend the systematic teaching intended for senior students which is still provided (and will be provided, I am told, as long as possible) at the London Hospital.

When allocating students to hospitals the Dean of the London Hospital Medical School endeavours to meet students' own wishes so far as possible in relation to the kind of work—i.e., medical or surgical—on which they ought to be engaged. On the other hand, the Medical School thinks it a mistake for any students to stay at one hospital for more than six months at a time. This organization is obviously an involved one, and means much travelling round to see how things are going on and a rather complicated change-over between hospitals at the end of each calendar quarter. It has, however, I am informed, worked satisfactorily and is fluid enough to be adjustable at short notice to meet any new situation which may arise.

Problems of the Future

So much for medical education in London to-day. But is it all that it should be? Is the best possible being done under the changed conditions consequent upon the war? In the London Hospital there were 850 beds available for clinical teaching before the war. In Sectors I and II there are now over 10,000 for acute cases, and the London Hospital Medical School is making good use of these. In some of the sectors there are many fewer beds, but I am not quite sure that all are being used to the fullest advantage for teaching purposes. Moreover, why must a medical school confine its students to the hospitals of its own sector? Surely teaching may be of value though it is not given exclusively by the staff of the particular hospital to which a student is attached.

Further, what will happen after the war? Shall we return to the system by which, with the exception of fevers, mental disease, and in some cases midwifery, the whole of a student's education takes place within the walls of a single hospital? Is there not a good deal to be said for three or six months being spent at a hospital in which ordinary everyday cases of general practice can be better studied? And if this be the case, at what stage should this resident appointment be fitted in? I know there are innumerable problems and difficulties—the already overburdened curriculum, the payment of the teachers, the time taken in teaching in relation to their other duties, etc. But all these are not insoluble, and the efficient training of doctors for the difficult years ahead is more important than them all.

Nova et Vetera

SEVENTY-FIFTH ANNIVERSARY OF THE "INDIAN MEDICAL GAZETTE"

The *Indian Medical Gazette* in its issue for December last published a brief history of the past three-quarters of a century to celebrate its seventy-fifth year of issue, about a quarter of a century less than our own *British Medical Journal*. It begins with a brief account of the advance in medical science made during that time, which includes practically all the modern developments, except vaccination, which was somewhat earlier, and goes on to an account of the growth and development of the *Gazette* itself.

During the past century dozens of medical journals have sprung up in India and had their brief day, usually petering out after a few years and now forgotten. The most successful of these was the *Indian Annals of Medical Science*, which started some ten years before the *Indian Medical Gazette* and lasted for about twenty years. But it was never exactly a newspaper; it was much more like a monthly magazine than a journal. There are a number of medical journals of sorts now running in India, some of which may perhaps last. About 1882 the late C. W. S. Deakin, I.M.S., started at his own cost and responsibility a periodical which began as the *Transactions of the N.W.P. Branch of the British Medical Association* and developed into the *Indian Medical Journal*. It ran for some ten years, but ceased to appear after Deakin's death. Dr. Wallace, a retired member of the Indian Medical Department, started a journal, the *Indian Medical Record*, in 1890, which began as a monthly, after three years became a fortnightly, and in 1899 a weekly journal. It ceased with Wallace's death in 1903, but was more than once revived for a time. In 1884 the Government of India began the publication of *Scientific Memoirs*, which came out at irregular intervals, usually roughly monthly. But this has never been in any sense a medical journal, but an issue of highly technical papers.

At the end of the article comes a list of editors, from 1866 to the present day. To two of these editors, who held office for a long time, the success of the *Indian Medical Gazette* is chiefly due: the late Brigade Surgeon Kenneth McLeod, editor 1871 to 1892, and the late Lieut.-Colonel Sir Walter Buchanan, editor 1899 to 1918—especially to the latter, who practically remade the *Gazette* and greatly increased its circulation.

THE HEFFERNANS

Major Patrick Heffernan has put his leisure to good purpose after his retirement from the Indian Medical Service. He has published a concise and well-written history of the Heffernan family.[1] It will be read with interest by many different classes of readers. The Heffernans occupied from time immemorial the tract of country lying between Tipperary and Limerick. They appear in history as large farmers, often above the average in culture, and filling many positions at home and abroad, beginning from very early times. Major Heffernan carries the story down to the present day. The most interesting chapter perhaps is that dealing with the clan system. He suggests that the derelict conditions so common in the south of Ireland are due less to the famine years in the middle of the last century than to the absence of the custom of primogeniture. A father could and did leave his possessions to any of his children; it might thus happen that no one had more than a life interest in the lands and houses, which were thus allowed to fall into disrepair. The theory is plausible and requires more thorough examination. Major Heffernan's book should appeal to medical men because so many of his family have been doctors, especially in the Indian and Army Medical Services.

Reports of Societies

THE EFFORT SYNDROME: ITS NATURE AND TREATMENT

At a meeting of the Section of Medicine of the Royal Society of Medicine on April 22, Sir MAURICE CASSIDY presiding, the subject of discussion was "The Effort Syndrome."

Dr. H. J. STARLING gave a historical review of the subject since 1864, at which time a committee considered it. It was then defined as "an extreme sensibility of the heart, with some but not great enlargement, and on the least exertion the action becomes irregular and the man becomes breathless." In spite of various publications on the "soldier's heart," few realized what it was and how to deal with it until the war of 1914–18. It was Sir Thomas Lewis who first described the condition as "effort syndrome" and instituted the only way by which it could be alleviated or cured.

With few, if any, exceptions, effort syndrome was primarily a civilian complaint. At least 50%—perhaps 70%—of the civilian population, when taken from their peaceful routine of life, were liable to this disorder, though they managed to do their daily work in their particular niche. At Colchester (1917–19) there were, however, a few outstanding men who at first glance looked different from the majority, and as though they ought not to be there at all. They had no tremor, but simply dyspnoea and tachycardia on effort. Almost invariably these were found to have some organic heart lesion, yet they had not been subjected to more strain in the Army than in civil life. In these cases it was not the physical but the psychical distress which produced the effort syndrome, and in most cases with the return to civil life it disappeared.

Since June, 1939, he had been engaged on this problem at the other end—namely, as chairman of the medical boards in a provincial city, where about 300 men per week were passed in various grades into the Service. He had been struck by the immense physical improvement of the men of 18 to 26, and their keenness on enlistment, whether as volunteers or under the Act, and it would be interesting to know whether this type afterwards yielded any considerable proportion of effort syndrome cases. The real national problem was not so much the cure or alleviation of the cases which arose as a result of the war, but the means whereby they might be prevented before war began. Convinced as he was that the disabilities were inherent in the civil population, he felt that the population must be trained in times of peace. The worst type of effort syndrome was found in the lad who was diffident and solitary, often spoiled by an indulgent mother, and much subject to minor infections.

The Emotional Factor

Dr. PAUL WOOD said that a review of English and American literature for the past eighty years, actual contact with some 300 patients, and certain researches had led him to some conclusions about this subject which would be published elsewhere. Here he would only indicate the general line of the argument. The incidence of symptoms in effort syndrome was, first, breathlessness in 93% of cases, palpitations in 89, fatigue or weakness in 88, sweating in 80, nervousness in 79, dizziness in 78, pain in 78, and other symptoms in lower percentages.

The symptoms and signs more closely resembled those of emotion, especially fear, in the normal person, than those of effort or heart disease. Researches into the behaviour of the pulse rate, sweating, breathlessness, and fatigue led to the conclusion that somatic manifestations were due to central stimulation, not to hypersensitivity of the peripheral mechanism. Direct evidence that this central stimulation was emotional was available. He drew special attention to the distribution of sweat in what he preferred to call Da Costa's syndrome. The palms of the hands, the axilla, and to some extent the brow were the usual sites. Such a distribution necessitated an emotional stimulus. On the other hand, if a cholagogic drug were administered, such as acetyl-beta-methylcholine, the distribution of the sweat followed the parasympathetic flush area, and left the extremities more or less free. When an experiment was carried out with this drug the controls sweated more than the patients. How these emotional reactions became linked up to effort was perhaps the crux of the situation. He urged that the diagnosis "effort syndrome" be dropped. A proper psychiatric diagnosis was nearly always available; if attention must be called to the presence of effort intolerance, let "effort intolerance" be added, preferably in brackets. If it was convenient at times to speak of all these cases under a group heading, why not "Da Costa's syndrome"?

Finally, he mentioned researches into left inframammary pain. This pain was not imaginary. No imaginary pain could be so consistent in its characteristics. It seemed to be muscular or ligamentous and related to respiration and to the fact that the heart was beating hard in its irritable fashion against the chest wall. In 25% of the cases the pain was bilateral, but the patients took no notice of the pain in the right mammary region, concentrating on the pain in the left and imagining it referable to the heart.

A Heterogeneous Condition

Dr. AUBREY LEWIS said that "effort syndrome" was a heterogeneous, not a unitary, condition, and therefore it did not deserve a unitary name. A uniform plan of treatment for all cases of effort syndrome would be neither ideal nor efficacious. Probably no one would argue that physical training and graduated exercises were the whole of treatment and not a part, but the emphasis given to them was exaggerated. Perhaps they were more useful diagnostically and prognostically than therapeutically. Sir Thomas Lewis and others had drawn special attention to the large proportion of these patients seen in the last war who had previously followed a sedentary occupation. The more carefully the symptoms were studied the more evident it became that this was not a local disability but a general disorder, influenced by local factors. Both physical and psychological disturbances were at work. Some of the patients were highly suggestible. Any subjective symptoms such as pain, discomfort, weakness, or fatigue would be influenced by the attitude adopted by those who inquired about the symptoms. The symptoms might be intensified or disposed of by the doctor, sometimes without his awareness of the influence he was having on the patient. There were almost always in the man's past both physical and psychological influences strongly represented in his constitution, which had so conditioned him that in the face of the rigors of war he developed symptoms of effort syndrome and tended to utilize them to escape from an environment which did not suit him.

There were only two things the doctor could do: he could either alter the man fairly radically or alter the conditions under which he served, and both these were difficult. To alter a man physically and psychologically so that he would put up with what he could not stand before was only occasionally possible, and alteration of environment was hampered by the necessary rigidity of military arrangements. The returns for a number of men whose history was inquired into six months or more after discharge from hospital to military duty showed that 30% were doing full duty efficiently and willingly, 36% had been discharged from the Army, and the remainder were doing light duty or were doing full duty not quite satisfactorily or had fallen ill again. The conditions to which the men returned would often decide whether they succeeded as soldiers or not, and some commanding officers were more adept than others in fitting these men in. Between one-half and three-fourths of the patients could have been got back to military duty of a type for which they were fitted, but this would have required a sorting of the men and an amount of military administrative procedure which were perhaps hardly practicable. There was very little evidence that these men as a group were physically inferior, and often it was found that in civilian life they had been doing work as heavy as or heavier than they were called upon to do in the Army. A relatively small physical disability was seized upon for emotional purposes and magnified. He added that the problem of effort syndrome bore the hallmark of a psychiatric problem—that is to say, it was an individual and at the same time a social problem, and must be dealt with on both individual and social lines.

Dr. MAXWELL JONES said that breathlessness was one of the main complaints in effort syndrome. It might come on at rest or on excitement, but according to the patients' statements it was more usually related to physical effort. The first point to inquire into was whether hyperpnoea in excess of normal was present after effort, and, if so, whether it could be estimated. He described a respiratory exercise tolerance test which he and his colleagues had devised to show any deviation from normal respiration. It was tried out with 32 patients and an equal number of controls, and the results showed that in fairly severe cases of effort syndrome there was a delay in the return of the volume to the resting level as compared with a group of normal subjects. There were also characteristic differences in respiratory style, vital capacity, and breath-holding in the cases of effort syndrome.

General Discussion

Colonel H. L. TIDY said that in the last war this condition, then known as "D.A.H.," became an extremely important matter; the element of fear was largely regarded as the causative factor. At present effort syndrome in this war was a relatively trivial concern. He believed that in this country only 200 beds were allotted to cases of effort syndrome, these relating to all the Services, and the beds were not all occupied. He thought that Army medical officers should not be encouraged to send cases of effort syndrome to specialists. Many officers had succeeded in getting the men through without sending them either for examination by a specialist or into hospital, and there was no doubt that a number of men were able to be acclimatized and to become useful soldiers, whereas if sent to hospital they would drift into the class of effort syndrome cases. In Sir Thomas Lewis's cases 50% were sent back to the front line, but it was not known what happened to them subsequently; no doubt some went again into hospital. It was an undoubted fact that a large number of these men were below the physical average, and their condition was not improved to any great extent in hospital.

Sir MAURICE CASSIDY said that he did not suppose many of those present ever saw these so-called "effort syndrome" cases in the last war before they went to Colchester. In 1915 and 1916 large numbers of men were to be seen who had been kept in bed for months with a persistent tachycardia—rates of 120 or even more. They reminded him of a second-hand car which he bought at that time. On asking his chauffeur what he thought of the brakes, he replied, "Well, sir, with this kind of brakes, the harder you press them the faster she goes!"

Sir ADOLPHE ABRAHAMS said that he, too, deprecated the term "effort syndrome," but he could not substitute anything more satisfactory, and its predecessors "D.A.H." and "soldier's heart" were very much worse because they concentrated attention on the heart, and the second of them suggested an occupational disorder. The term "effort syndrome" would be more acceptable if it were quantitative, as some people had the impression that it was—in other words, that a minimal effort in these subjects produced the same train of symptoms as were produced in anyone if the exercise was sufficiently severe. But the symptoms which occurred in these people had nothing to do with effort, and the large majority of them could never be produced by effort, however severe, in a normal subject. Even breathlessness in a physiological sense was a different phenomenon from what was seen in these cases. On occasion one might see a great athlete tremulous, sweating, shivering, and completely incapable of any physical effort; but that had nothing to do with effort, it was simply the prospect of an ordeal, and the same train of symptoms might be produced in a person who was about to make a speech or enter for an examination. A number of different things had all been lumped together because they had the same symptomatology and to a certain extent the same physical signs. But gradually order was coming out of this chaos. The workers were isolating certain groups which could be explained. It was true that there was a baffling residue, whose incapacity for exertion, symptomatology, and physical signs were not explicable. He always had the hope that if they were explicable a great deal of normal physiology would be learned from them.

Major GERALD SLOT said that cases he had seen were not always in the new recruits; they were often men who had been in the Army since the beginning of the war, and a good many of them seemed to date their trouble from Dunkirk. On going back a little into their history it was sometimes found that they were temperamental, emotional, and unlikely to stand up to stress and strain. It was idle to send these people back to their units; they would only be sent somewhere else within a short time. Hospital treatment did not seem to be successful. They got better in hospital, but the condition recurred after discharge. It was well to be on the look-out for thyrotoxicosis in cases bearing this label, and also to be aware of the possibility of early tuberculosis. As for left inframammary pain, he had been able in many such cases to elicit a history of fibrositis.

Major C. HEWITT ATKINSON said that he did not think it was sufficiently explained to these patients that anyone undergoing mental or emotional strain also went through a physical effort. The patient was puzzled by his palpitations, and a proper explanation of the symptoms helped towards reassurance and recovery. "Effort syndrome" was a wide term. He was accustomed to think of these cases in three groups. The first consisted of the true effort syndrome case, in which the patient had been through a severe ordeal and showed signs of cardiac strain. The second consisted of those who came up primarily anxious about their heart (the characteristic individual was the over-strained student). The third class consisted of those in which infection was present.

Major GEOFFREY KONSTAM said that if any progress was to be made certain definite limits must be laid down. He would eliminate cases of pure anxiety neurosis without particular symptoms of effort and also the pure cardiac neurosis. Dr. Paul Wood had exhibited to the meeting a painting of a patient at Mill Hill illustrating what he considered to be the typical constitutional case—the strained features, the slumping posture, the flat chest. In Major Konstam's view the rather placid face in this portrait did not illustrate the condition. In the typical case he had been struck by the corrugations on the forehead, both horizontal and vertical.

Dr. STARLING, in reply, taking up Dr. Paul Wood's suggestion that the term "Da Costa's syndrome" might be used, hoped that no more syndromes or diseases would be described by a person's name.

DEATH AFTER DELIVERY

At a meeting of the Section of Obstetrics of the Royal Academy of Medicine in Ireland on March 14, the chair was taken by the president, Dr. R. M. CORBET, and Dr. J. G. GALLAGHER read a review of some of the causes of maternal death shortly after delivery.

Nearly all his cases came under the heading of "obstetric shock"; they had occurred in the Dublin maternity hospitals during the last five years. Among 52,000 deliveries there had been 248 deaths, 74 being due to haemorrhage and shock. A search for a common factor had shown that 30 deaths had followed manual removal of retained placenta, that ante-partum haemorrhage had been a factor in 25 cases, and that anaemia had been the main factor in 6 deaths and important in 8 others. The remedy for anaemia was more widespread ante-natal care and better all-round nutrition. Many of the patients with ante-partum haemorrhage had been received in a dying condition; both transfusion and section had had a fair trial. Placenta praevia had caused death from bleeding in 8 cases. Twelve patients had died of shock from abruptio placentae, and there had been 5 fatal cases of external accidental bleeding. The mortality of manual removal of the retained placenta was 11 to 15%. Death was apparently due to shock in 25 cases, in 18 of which there had been no post-partum haemorrhage and a normal second stage. Five deaths had been due to sepsis. The real danger of operation was shock. Plasma transfusion might improve the results. Crede expression and intracordal saline had been associated with 2 deaths each. In addition to these three groups there had been post-partum bleeding in 22 of the cases, severe in 6; 7 cases of ruptured uterus, one of acute inversion; 6 of craniotomy, 9 of version, 7 of section operation, and 1 breech

extraction. There had been 19 forceps cases, in 5 of which the forceps had failed to deliver.

Dr. BETHEL SOLOMONS said that with very few exceptions the term "obstetric shock" would not be used to describe the cause of death; it meant that the obstetrician did not know why the patient died. To ascribe death to obstetric shock in cases of ruptured uterus, concealed haemorrhage, and failed forceps would be to prevent research which might lower mortality. Manual removal of the placenta was a disease of the junior obstetrician. A really adherent placenta rarely occurred at the first birth. Conservative measures gave much better results than Caesarean section in concealed accidental haemorrhage. He hoped that the injection of submammary saline was still taught for district work; pituitary shock would not occur if the extract were given after the placenta was delivered.

Dr. T. M. HEALY agreed that obstetric shock was a rare condition; he thought that many of Dr. Gallagher's fatalities were due to traumatic shock. It was exceedingly difficult to know what some of these patients died from; it would be a great comfort to obstetricians to know why, when patients bled into their tissues or into the peritoneal cavity, they got into such an extraordinary state of collapse after such small loss of blood.

Dr. O'DONEL BROWNE felt very strongly that the term should not be abandoned, and stressed the necessity for sharp distinction between it and the collapse or shock of excessive bleeding. He thought that Dr. Gallagher's summary indicated, as significant aetiological factors, ill-health before the confinement, prolonged labour, misapplied obstetric operations and bad obstetrical judgment, exposure to cold, and prolonged anaesthesia, but these factors would not of themselves precipitate the condition without concurrent tissue damage. He thought that pituitary shock was overestimated, and that judicious use of pituitary extract was a great asset in the treatment of shock. He had never known a case of traumatic post-partum haemorrhage where bleeding from a torn cervix demanded suture, and wondered whether the cases treated by cervical suture were not really incomplete uterine ruptures. Dr. A. SPAIN said that the mistake was to use the term "obstetric" in this condition; most of the patients had died from a shock which was in no way different from shock due to other conditions. Shock was a very definite clinical entity. In most cases manual removal of the placenta should be done earlier than it was. Dr. F. W. DOYLE believed that obstetric shock undoubtedly did occur, and described a case. He thought collapse and shock were two different conditions with many features in common. Dr. E. A. KEELAN said there must be a small group in which maternal mortality had its inception in the first stage of labour—for example, primiparae who did not obtain adequate rest, sleep, or food in the first stage, whose improper feeding produced vomiting, often persistent, or who were told to bear down too early. The result was maternal distress and premature termination of the second stage. Dr. D. F. HANLEY noted that all Dr. Gallagher's patients had been wounded in some way. The shock complex seemed to be secondary to some kind of trauma.

The PRESIDENT said that the records of the Coombe Hospital for the last five years suggested that patients who died shortly after delivery could be grouped into three classes: those with organic disease (9 cases), those with grave abnormality of pregnancy (8 cases), and those who had no complications before the onset of labour (1 ruptured uterus, 1 pulmonary embolus, and 4 cases of obstetric shock). He would reserve the term "obstetric shock" for those cases which had an atraumatic delivery without post-partum haemorrhage. He had long disbelieved in its existence, but had been forced to accept it. The consulting obstetrician was called to a patient in a terminal condition which might have resulted from either shock or haemorrhage, and had the grave difficulty of diagnosing between them. Manual removal was not associated with any mortality if undertaken for post-partum haemorrhage due to partial detachment of the placenta. It had a high mortality in patients who had developed shock without any adequate haemorrhage, but he was not satisfied that the mortality would be reduced by leaving the placenta in a patient whose shock was becoming progressively worse.

Dr GALLAGHER, in reply, said that submammary saline was slow and much more unpleasant for the patient than subcutaneous saline. He thought it would be difficult to find a short term to replace "obstetric shock."

Local News

ENGLAND AND WALES

Healthy London

The health record of London for 1939, the year in which a city devoted to the arts and services of peace switched over to a war footing, was remarkably good. This is the conclusion to be drawn from the very attenuated interim report for that year of the County Medical Officer of Health and School Medical Officer (Dr. W. A. Daley).[1] Infant mortality stood at the lowest figure ever reached—47 per 1,000 live births. Infectious diseases were all at the ebb, except for a trifling increase in the notifications of encephalitis lethargica and a rather considerable increase in the number of deaths from influenza. The number of notifications of diphtheria was down by more than one-half and those of scarlet fever by nearly one-third as compared with the year before. The number of deaths from pulmonary tuberculosis was virtually unaltered, but the primary notifications were lower. On the registers of London boroughs the number of cases of pulmonary tuberculosis stood at 23,000, and those of other forms at 6,700. An immediate effect of the war was a dislocation of the tuberculosis dispensary service and also the discharge of 1,750 patients from residential institutions in order that beds might be reserved for Service or civilian casualties. There was also a decline during this year in both notifications of and deaths from puerperal fever and pyrexia, this in spite of the fact that the number of beds available for maternity patients in London hospitals was materially reduced so that an increased proportion of confinements took place at home, many of them attended by the council's domiciliary midwives, who now number more than 100. Many important schemes of improvement and development in the county hospitals of London had to be abandoned on account of the war. All the patients in the general hospitals for acute cases who were reasonably fit for discharge, 4,000 in number, were sent home; others were transferred to hospitals outside the county boundary; and there remained 4,000 who could not be moved, while 7,600 beds were made available for air-raid casualties. But the expected air raids did not occur, and some acute sick were readmitted. The number of patients urgently requiring treatment who were admitted to the general hospitals during the last three months of 1939 was 29,500, or three-fourths of the number admitted during the corresponding period of 1938. The number of sick admitted to the special hospitals fell from 53,000 to 32,000 for the whole year. This includes the infectious diseases hospitals, where the number fell from 40,000 in 1938 to 21,500 in the following year. The reason for this is, of course, the decline in the child population of London under the Government evacuation scheme, but the low incidence of infectious diseases among the remaining population had something to do with it. The most complete dislocation occurred in the school medical service. With all the schools in London closed, and the school population, normally 435,000, reduced to 180,000, there was at first an entire eclipse of school medical work. But by November many of the school treatment centres were reopened, and by the end of the year nearly one-half the eighty minor ailments centres were functioning. While there was still no regular schooling the school medical service was in active operation. During the first two terms of 1939 over a quarter of a million children were medically inspected, nutrition was pronounced satisfactory in over 93%, and general health was good, showing in nearly every particular a slight improvement over previous findings.

Grants by the Nuffield Provincial Hospitals Trust

The trustees of the Nuffield Provincial Hospitals Trust have made a number of grants for hospital and ancillary medical services. They have authorized a substantial grant to the

[1] London County Council. *Interim Report of County Medical Officer of Health and School Medical Officer for 1939.* Westminster: P. S. King and Son, Ltd. (6d.; post free, 7d.)

Birmingham Accident Hospital as a practical expression of their desire to promote the establishment of efficient fracture services. The grant is made on the condition that the balance of the initial capital expenditure necessary to convert the old Queen's Hospital into the new Accident Treatment Centre is forthcoming from other sources. They are also making a contribution towards the capital cost of an Accident Treatment Centre in Oxford, proposals for which have been approved by the Berks, Bucks, and Oxon Regional Hospitals Council. Proposals have been prepared by the Medical Advisory Council of the Trust for a regional pathological service to provide complete, co-ordinated, and effective laboratory services for both public health and clinical pathology. The trustees have authorized a grant of £1,500 to the Regional Hospitals Council of the Berks, Bucks, and Oxon area towards the capital expenditure of the service. It is considered that valuable experience may be gained from this which will furnish a guide for future action in other regions. Financial provision is also being made by the Trust for a cancer survey to be undertaken in two regions. The trustees consider that the success of the scheme for the regionalization of hospital and medical services depends, to a large extent, upon the active, intelligent, and sustained co-operation of the general practitioner. It has accordingly been decided to adopt a scheme, experimentally in the first instance, in the area of the Oxford and District Joint Hospitals Board, for a medical liaison service. Under this scheme one or more retired medical practitioners will be appointed to act as liaison officers between the joint board and the general practitioners in the division. The cost of the scheme for the ensuing year will be defrayed by the Trust. A grant of £2,000 per annum for three years has been made to the Prince of Wales's Hospital, Plymouth, for allocation through the South-Western Regional Hospitals Council, subject to a satisfactory arrangement being made between the hospital and the Corporation on the co-ordination of hospital services in Plymouth and to an agreement between the Plymouth Corporation and the Devon and Cornwall County Councils as to the payment of contributions to the Prince of Wales's Hospital. A grant of £2,000 has also been made to the Royal Berkshire Hospital for the current year, and a further grant of £1,000 for a second year, subject to certain conditions.

Hospital Regionalization Conference in Liverpool

A conference has lately been held at Liverpool on the invitation of the Vice-Chancellor of the University (Dr. A. D. McNair) to discuss proposals from the Nuffield Provincial Hospitals Trust for a regionalized hospital service in the north-west. It was attended by representatives of the Trust, the Liverpool Hospitals Joint Advisory Committee, and the local authorities and voluntary hospitals of Lancashire and Cheshire, North Wales, and Westmorland and Cumberland. The Vice-Chancellor stated that some months ago the Trust approached the Advisory Committee, which represented both the municipal and the voluntary hospitals of Liverpool, asking whether the necessary steps might not be taken to form a hospital region based on Liverpool and its university medical school. The committee examined the proposals and decided to give effect to the request, with the result that the conference was called, not to accept a cut-and-dried scheme, but to consider the principle of regionalization as applied to the area. Addresses were given by Mr. W. M. Goodenough, chairman of the Trust, Sir Farquhar Buzzard, chairman of its Medical Advisory Committee, and Mr. S. Richardson, chairman of its Provincial Hospitals Regional Committee, and the conference was then thrown open. While the principle of regionalization was generally supported as a means of better co-ordination between voluntary hospitals and local authorities, it was felt that those present had no mandate to vote, and on the motion of Prof. Henry Cohen it was agreed, while expressing the desire of the conference to examine sympathetically the principle of regionalization, to adjourn to a later date so that the representatives of local authorities and voluntary hospitals might consult their constituents and obtain such a mandate. The chairman of the Birkenhead Health Committee, Councillor H. Bullock, said the lack of co-operation hitherto was due largely to the attitude of the voluntary hospitals, and he asked whether those hospitals would still be allowed a preferential position in regard to training, nursing staffs, and patients, and whether redundant hospitals would be scrapped. Sir Farquhar Buzzard replied that such questions could only be decided by the regional councils themselves. There was no desire to aggregate all consultants in one place, but rather to distribute them wherever needed.

SCOTLAND

Glasgow and the E.M.S. Hospitals

At the annual general meeting of Glasgow Royal Infirmary, at which the Lord Provost, Sir Patrick Dollan, presided, Sir William Marshall, referring to recent speeches of the Minister of Labour concerning the man-power of the country, said he could not help thinking of the incapacity through illness which prevented a large section of the people from doing their best in the national effort. It was stated that in this country on any day throughout the year 650,000 of the working population were away from work on account of unfitness. He believed that much of this incapacity need not exist if the medical and surgical services were immediately available for efficient treatment. A great army of workers might be pulling their full weight were it not for the fact that they could not obtain the treatment their medical advisers considered necessary for the restoration of capacity. Some of the emergency hospitals had very few or no patients. If there had only been some loosening of the restrictions regarding empty beds in emergency hospitals a large number of civilian patients would have been made fit for their work to-day. Sir William Marshall welcomed, as did Mr. Charles Glen, chairman of the Glasgow Royal Infirmary, the steps taken by the Department of Health to have waiting patients received in the emergency hospitals.

Bequest to Edinburgh for Medical Research

By a judgment in the First Division of the Court of Session, Edinburgh University becomes entitled to the whole residue of the estate of the late Mr. John Risk, a distiller of Stirling, to be applied for the advancement of medical and surgical research. By his trust disposition Mr. Risk directed that in certain events his trustees should pay one-half of the residue of his estate to the surviving issue, if any, of his daughter, or, in the event of there being no such issue, the whole residue to the Court of the University for this purpose. He also declared that should his daughter repudiate the settlement and claim her legal rights she and her issue should forfeit all rights under the settlement. Miss Risk did in fact claim her legal rights. It was agreed between the parties that the trustees were entitled to divide the estate remaining in their hands into two equal parts and to pay one of such parts to the University, but with regard to the other it was contended on behalf of Miss Risk that the trustees were not entitled to pay it away so long as it remained uncertain whether or not she would be survived by issue. The Division held that the University Court was entitled to payment of this second part of the residue.

Edinburgh Medical Missionary Society

The Edinburgh Medical Missionary Society will celebrate its centenary on St. Andrew's Day this year. Beginning in a small way its work and fame grew, and it has been the means of helping well over 300 medical students to train as doctors for the mission field under different religious denominations. It has also maintained hospitals in Nazareth and Damascus. To commemorate the first hundred years Dr. H. F. Lechere Taylor, a former secretary and superintendent, has written an outline of the history and activities of the society under the title *A Century of Service*. During the earlier years it was known as the "Edinburgh Association for Sending Medical Aid to Foreign Countries"; the present title was adopted in 1843. In 1861 the society took over the Cowgate Dispensary in Edinburgh. Extensions of the premises have included the Livingstone Memorial Medical Missionary Training Institution. It was in 1853 that the society sent its own first medical missionary to India.

Correspondence

"Bureaucratic Surgery"

SIR,—Mr. Norman Lake's letter has anticipated two short papers that I had in preparation—one on the treatment of scalp wounds, the other on the part that neurosurgery is playing in the present war. These might have forestalled some of his criticisms. I doubt whether Mr. Lake really objects to organization, though he clearly resents some of its results.

In brief, the reasons for the segregation of neurosurgical cases were twofold: first, the belief that they would be more competently treated and more fully investigated with regard to their present and possible future pensionable disabilities if they were in the hands of those who spent their lives at the work; second, the furtherance of research.

Once it had been decided to open these Centres the next question was, What types of injury were to go into them? This is, as Mr. Lake admits, a difficult one. Yet it was fundamental and it had to be answered. The only safe way was to ask that all head injuries, both slight and severe, should be sent. And in order to get a cross-section on the casualties notification of head injuries was set up. This was an excellent arrangement, for how otherwise was it to be learned what the incidence of the injuries was, what were their types, how many required operation, what was their mortality?

Experience was showing that even the scalp wounds were not being treated as well as they might have been. The simple scalp wound, about which one can in theory become so irate, is an abstraction. These wounds when inflicted under war conditions have commonly been produced by a force much more severe than those of peacetime, and complications are more common. I drew attention to this fact in a special paper in 1919. In the present war cases came into the Centres with missiles in their brains and with their wounds unexcised and septic. It is no use objecting that these were not scalp wounds; they were taken for such and treated as such in the receiving hospitals until the error was perceived. I have no doubt that Mr. Lake and others of his standing and skill would not, and do not, make these mistakes. But the fact of importance is that some persons do so. How, I ask, would Mr. Lake have solved these difficulties, not in the light of theory but with actual experience before his eyes? I would remind him that his ruling would have to cover not only the London teaching schools, the great schools of the Provinces, but also the large towns, the small towns, the cottage hospitals. No one can pretend that experience and ability are evenly distributed throughout the countryside, yet a ruling has to be made for all. I have always been aware that the order contains in it a germ of the ridiculous, but it was felt that the rule would be applied with common sense, and the trivial bumps and scratches would not be sent in. Mr. Lake can rest assured that this is so. It is clear that many surgeons feel some resentment, even an affront to their reputations, at what they call their "cases being taken from them." This is a sentiment shared alike by the less expert as well as by the good surgeon. How can a clear, workable, but not invidious, ruling be made, how precisely can exemptions be given, and to whom? And what will be the effect of these when it becomes known that So-and-so has been given permission to be the complete individualist and specialist in this or that or even to be a multi-specialist when So-and-so has not? What is more, the dispersal of cases into many hands makes co-ordinated research well-nigh impossible. This brings me to the other reason for the Centres beyond that of pure organization for practical purposes. The only way to further research, for which the present times offer unique and, we trust, non-recurring opportunities—for example, on the effects of the new antiseptics on brain wounds and meningitis as well as on neurological problems generally, such as the cortical electro-potentials after injury—was to collect the cases together. Several of these Centres are doing research of some kind or another with help from the M.R.C., and in order to obtain an unselected material for study both the slight as well as the obviously severe injuries must be gathered together. This was the reason for the setting up of the few peripheral nerve centres of which Mr. Lake also complains. It would have been a disaster if the Ministry had paid no heed to such projects because of the possible future objections of the few. Nor could the Medical Research Council have given its valuable help economically if the work had gone on in a plurality of places.

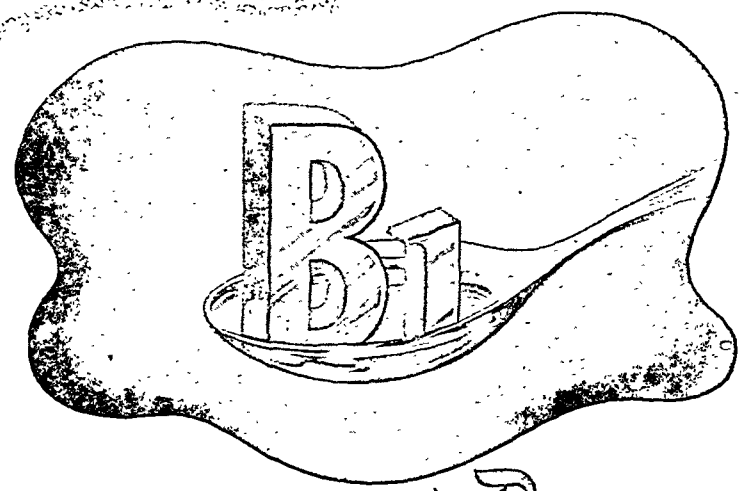
I believe that some of Mr. Lake's objections might have disappeared, or been less bitterly expressed, had he known what the ideas were behind the shortly worded and, I admit, not very explanatory requests that have doubtless come his way.

The wider issue as to what the future holds in the way of State medicine must be left. But I imagine and hope that the patient will be entirely free in his choice of doctor or surgeon. The war casualty is not in a position to choose; and the surgeon looking after him is, in regard to that patient, without vested interest or possession.

The exigencies of wartime have severely limited opportunities for discussion between ourselves in the ordinary way, hence misunderstandings. But it would be too much to hope that any arrangement could be arrived at, by any means whatever even in peacetime, that would find no critics, no dissenters.—I am, etc.,

Manchester, April 21. GEOFFREY JEFFERSON.

SIR,—In his letter Mr. Norman Lake echoes the sentiments of all his colleagues when he expresses his desire to see the Emergency Medical Service as perfect as possible from the patient's point of view. Yet if we will the end we must be ready to adopt the necessary means, and, as one who is quite as critical of the bureaucrat as Mr. Lake can be, I venture to submit to him that we must judge any therapeutic instruction or recommendation upon its merits, and that we may not dismiss it as a piece of medical bureaucracy simply because we distrust the channel through which it reaches us. Here at least is an opportunity for the use of that sound judgment which Mr. Lake—bolder than I—claims by implication for all senior members of voluntary hospital staffs.



In the particular matter of the instructions upon the treatment of head injuries to which he objects, Mr. Lake may possibly be willing to concede to me, who am neither bureaucrat nor neurosurgeon, a dispassionate point of view and one founded upon some experience. Through the courtesy of a surgical colleague I have had the opportunity in the special "head centre" of an E.M.S. hospital to see a considerable number of recent cases of head injury of all grades of severity. This experience has fully convinced me of both the need and the soundness of the instructions referred to adversely by Mr. Lake, and it has led me to the two following conclusions:

1. That hitherto we have all been very ignorant of the incidence, range, and character of the abnormal neurological signs that may accompany apparently trivial scalp wounds unattended by evidence of cranial injury; and that such signs are to be found in a considerable proportion of such cases by those who, trained to elicit them, make a systematic search for them.

2. That, despite the issue some considerable time ago of recommendations for the initial treatment of head injuries, these recommendations are not being as generally adopted as is desirable, with the result that in a proportion of cases the period of treatment and of disability is unnecessarily lengthened and the final prognosis adversely affected.

Facts substantiating these conclusions are shortly to be published by the surgical colleague to whom I have referred.

If these conclusions are sound, no general surgeon can reasonably resent the inference that the surgeon with special experience in craniocerebral surgery is best placed to detect the signs of damage to the brain in apparently trivial head injuries and to formulate rules for the most effective treatment of the latter. That such rules must of necessity in the present circumstances be issued through a Government Department does not permit us to dismiss them as mere bureaucratic interference with medical judgment. To tilt at specialists is an amusement as easy and as unsatisfying as calling grapes sour, but since the subject is raised it may not be amiss to point out that if there be a man more dangerous than the too exclusive specialist it is he who desires to be thought a specialist in every branch of our art and will learn from no one. A considerable experience as a spectator of craniocerebral surgery and its results has convinced me that the theory and the

Increased Dosage

In view of the trend towards increased dosage of Vitamin B_1 both here and in the U.S.A. it has been decided to raise the strength of 'Betaxan' tablets from 1 mg. to 3 mg. pure synthetic crystalline Vitamin B_1 and the strength of the 2 mg. ampoules to 5 mg., and of the 10 mg. ('Forte') ampoules to 25 mg.

'Betaxan' tablets will now contain *three times* and 'Betaxan' ampoules *two-and-a-half times* the amount of Vitamin B_1.

As no increase in price will be made, these greater strengths constitute a considerable reduction in price. The 1 mg. tablets are available at reduced prices.

PACKINGS:

'Betaxan' tablets 1 mg. and 3 mg.
Tube of 20, Bottles of 100 and 500

'Betaxan' ampoules 5 mg. and 25 mg.
Boxes of 3 x 1 cc.
,, ,, 15 x 1 cc.
,, ,, 50 x 1 cc.

So long as stocks last 2 mg. and 10 mg. tablets will be available.

Now made in England

practice of this branch of surgery are safest in the hands of the specialist, and the general surgeon need suffer no loss of dignity, no matter what his years, in learning from him what he has to teach.

No one seeing large numbers of cases of head injury resulting from air raids can doubt the seriousness of the problem of examination, assessment, and treatment they provide. We shall do ourselves less than justice if, through a false sense of dignity, we decline to avail ourselves of advice that, through whatever official channel it reaches us, is certainly the fruit of the ripest experience.—I am, etc.,

London, W.1, April 23. F. M. R. WALSHE.

Reception and Treatment of Air-raid Casualties

SIR,—Among recent interesting contributions to the *Journal* on the reception and treatment of air-raid casualties, a subject of considerable moment to all those of us called upon to carry out this duty, Mr. John Robert Lee's description (April 19, p. 584) of his routine stands out by virtue of its restraint and accuracy. The desperate conditions under which he has worked are only too well known to most of us. His classification of casualties is the one which circumstances dictate; his care for the individual patient (so rare in these days of schemes) is obvious; and how true his statement that methods successful in the proper treatment of road, rail, and machinery accidents are equally successful for the even more serious air-raid injury! Sulphanilamide is not an easy substitute for the meticulous excision and suture of wounds, but a means of avoiding infection in those cases where it is impossible to carry out the counsel of perfection.

Three of Mr. Lee's remarks interested me particularly as reflecting my own state of mind. The effort to avoid amputation is always worth while, and, as he states, is nearly always successful. We also have struck the idea of two surgeons operating on one patient with multiple injuries and the results are gratifying, particularly when one of the lesions is abdominal. Mr. Lee likes to keep Group 3 cases under his own care; so do we all, and the moving of a patient bombed and operated on within twenty-four hours horrifies me more each time it recurs. The inevitability of the recurrence is even more horrifying. Surely the powers that be should realize by now that the right place to treat air-raid casualties is somewhere outside the bombed area, not in it.—I am, etc.,

Liverpool, April 21. E. N. WARDLE.

Renal Failure in Air-raid Casualties

SIR,—I have been interested to read reports in your *Journal* of air-raid casualties treated by intravenous injections of fluids in the presence of renal failure. It may not be out of place for me to record my own conclusions concerning the intravenous administration of fluids in relation to renal failure, coming on post-operatively in urinary cases.

Renal failure is sometimes not only made worse but is actually initiated by intravenous fluids administered either too generously or too quickly. Because of these consequences, while the drip is going on a careful check must be kept on the urinary output, and if this is found to be in abeyance it might well be asked, What is becoming of the fluid that is being put into the patient's vein? The strong suspicion that it is collecting in the various organs and tissues of the body should be a sufficient reason for discontinuing the transfusion. My own rule in treating renal failure is not to give more than a total of two pints administered continuously over a period of eight hours, and to abandon this form of treatment entirely if there is no important increase in the volume of urine after the patient has received twenty ounces of fluid continuously administered in the course of four hours (rate of drip, 40 drops per minute). For, in such circumstances, to persist with the transfusion to any considerable extent, in my experience, invariably leads to widespread oedema and death. Post-mortem examination in such a case will show that the kidneys have shared in the general oedema, and thus further interference with function has occurred of organs of which the activity had already been impaired.

Under war conditions the danger of renal oedema occurring in some cases of injury with shock certainly also calls for the most careful control of intravenous administration.—I am, etc.,

London, W.1, April 23. H. P. WINSBURY-WHITE.

Crush Injury and Experimental Uraemia

SIR,—It was with great interest that I noticed reports of a series of cases of renal failure following crush injuries in your issue of March 22. Although this syndrome is new to clinical experience it is already quite well known in the realm of experimental medicine. I feel that it is important that this work should be brought to light at the present moment, as it may prove of use in the treatment of future air-raid casualties.

All who are interested in this condition will be well repaid by consulting an admirable and most comprehensive article on experimental uraemia by E. Andrews, in the *Archives of Internal Medicine*, vol. 40. He first showed, in experiments carried out on dogs, that the total amount of water it is possible to make an animal excrete by the kidneys by injecting hypertonic saline was proportional to the CO_2-combining power of its blood, and that when a tourniquet which had been tightly applied to the leg was released there was a fall in the CO_2-combining power and urinary output. The mechanism whereby this arrest of urine formation was brought about was considered to be due to the liberation of lactic acid into the circulation from the damaged muscle, in which there seems to be some defect in glucose oxidation with the tourniquet applied. By a combination of these two experimental procedures it was possible to reproduce a practically perfect picture of the "uraemic syndrome." Many of the signs were caused by upset of the mineral salt metabolism and the ensuing altered cellular permeability.

R. N. Bieter, carrying out direct microscopical observations of the living frog's kidney, demonstrated a reduction in the number of glomeruli showing active circulation following the release of a tourniquet. This effect could be prevented by cutting the sympathetic chain (*Amer. J. Physiol.*, 91). I had myself in 1936 the opportunity of verifying these latter observations, and I also made a few additional ones of my own. I found that in the glomeruli whose activity had been arrested by the release of a tourniquet the capillary loops were distended with red cells, unlike the normal functional intermittency exhibited by the glomeruli of the frog's kidney, in which the capillaries are constricted and contain only a few red cells. If the animal was excreting a dye such as phenol red when the reduction of functioning glomeruli occurred, it was seen to become concentrated in the distal convoluted tubules, appearing as dark red streaks. It was usually impossible to attach a tubule to any particular glomerulus, but with the return of the circulation the dye was seen to be washed out. The concentration was very high in the distal tubules during the period of stasis, due to both the absorption of water and the secretion of the dye, so that any toxic substance present would probably reach a fairly lethal concentration capable of damaging the tubular epithelium.

I trust that these references may be of some use to those investigating this problem.—I am, etc.,

HUGH MILLER.
March 31. Surgeon Lieutenant, R.N.V.R.

Volume of Transfused Fluids

SIR,—Prof. H. A. Harris, writing in the *Journal* of March 29 (p. 491), comments upon the treatment of air-raid casualties described in a recent paper by Bywaters *et al* (*Journal* March 22). He objects in particular to the volume of fluid injected, and makes a plea for peace, quiet, rest, and non-interference in the resuscitation of the severely injured. While all will agree with the first three, the last, if it means withholding the benefits of early and rapid fluid replacement, will entail the loss of many lives, as anyone will testify who has watched the almost magical return from the apparently moribund of severely shocked casualties treated by rapid transfusion of blood and plasma. This was illustrated most forcibly by a recent case.

A flight lieutenant sustained very severe multiple compound fractures of both legs below the knees at 11.30 p.m. Morphine and first aid were given on the spot, and he arrived in hospital at 2 a.m. after a ten-mile journey over country roads. He was then grey, cold, sweating, almost pulseless, blood pressure ? 30. Transfusion, warmth, further morphine, and oxygen

by B.L.B. mask were immediately started, and his subsequent course was as follows:

Time	Fluid 1 bottle = 540 c.cm.	B.P. Systolic	Pulse Rate	Transfusion Rate
2 a.m. ..	—	?30	—	
2.15 a.m. ..	Plasma 1 bottle ..	70	150	Given rapidly
2.30 a.m. ..	Blood 1 ,, ..	85	145	Great improvement in colour and temp.
3.15 a.m. ..	Blood 1 ,, ..	95	145	
4.30 a.m. ..	Plasma 1 ,, ..	110	140	Fast drip
7.30 a.m. ..	Blood 1 ,, ..	90	130	Slow drip
10.30 a.m. ..	Blood 1 ,, ..	120	135	
12 noon ..	Plasma 1 ,, ..	120	130	

He was then considered fit for operation, which consisted of rapid excision of his extensive wounds, local application of sulphapyridine powder and vaseline gauze, and closed plaster, under nitrous oxide and oxygen. Bleeding was not marked, but there was a progressive fall in blood pressure to 85. Transfusion was continued with blood as a fast drip:

Time	Fluid	Systolic B.P.	Pulse Rate	Transfusion Rate
1.00 p.m. ..	Blood 1 bottle ..	85	150	Fast drip
6.00 p.m. ..	Plasma 1 ,, ..	120	145	Slow drip

The transfusion was then stopped; oxygen was given continuously throughout the day. Next day he was remarkably well, blood pressure 135 (his normal pressure is 140), but pulse rate still 140. Ten days later he was still progressing favourably, but as his haemoglobin was then 45, a three-bottle slow-drip transfusion of fresh blood was given.

This case illustrates the following points: (1) The value in severe shock of immediate massive transfusion. He had 2,700 c.cm. of fresh Group O blood, and 2,160 c.cm. of (pooled) plasma—a total of 4,860 c.cm. in sixteen hours. (2) The importance of controlling such transfusions by serial blood-pressure readings. (3) The unreliability of the pulse rate as an index of recovery from shock. (4) The number of donors involved in the treatment of a single severe casualty—in this case approximately twenty. (5) The enormous loss of fluid which must take place in severe multiple injuries. The patient described is slightly built, weight 10½ stone, and his normal blood volume cannot have been more than about 5,500 c.cm. If he bled 2,000 c.cm. at the time of injury, and a further 500 c.cm. at operation, the remaining 2,300 c.cm. represented plasma loss into the traumatized areas. It is my experience, and that of others (Whitby *et al.*, 1941), that the usual volume of fluids required to resuscitate the severely shocked is approximately four bottles (2,160 c.cm.), and the case described is atypical in that the patient required more than double this amount.—I am, etc.,

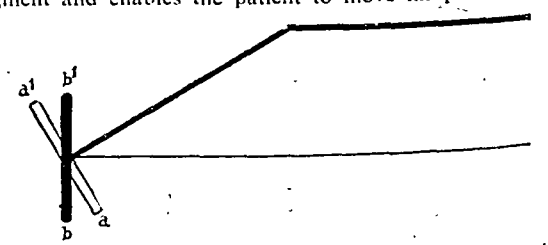
W. WYNNE WILLSON,
Captain, R.A.M.C.
April 25. Army Blood Transfusion Service.

Treatment of Burns

SIR,—Dr. E. C. Dawson, Mr. C. C. Holman, and Dr. George Adam (April 19, p. 602) raise questions which are ever present in the minds of those of us who are working on burns.

I do not think it can be too frequently stressed that so far as treatment is concerned burns fall into two main categories. The first category consists of those in which there is partial skin destruction only. Regeneration will occur under any method of treatment, and it is only necessary to avoid the infliction of further damage by either coagulation or the frequent repetition of adherent dressings. For this class of burn, therefore, there would appear to be no particular argument for or against the use of paraffin wax, vaseline packs, adhesive tape, or even plaster. Some of these substances will not be applicable in all areas and none of them appear to me to be ideal. In the treatment of burnt hands conservation of joint function is so essential that particular care must be taken to avoid any method which limits joint movement, and up to the moment it seems certain that the best method of treatment consists in the use of saline baths. This also presents technical difficulties which may prevent it from being universally applicable. A more perfect treatment would, I think, be a completely elastic, occlusive, antiseptic dressing which could be easily applied and, if necessary, easily removed. It should not interfere with epithelial regeneration and should be sufficiently stable to remain in place without protection for at least ten days. These desiderata sound simple, but there are many technical difficulties which I hope will be shortly overcome.

The second category of burns is that in which skin destruction is complete. If the area is small any method will allow slow centripetal regeneration. If the area is large this cannot be expected to occur and grafting will be necessary. Our aim is to do this at the earliest possible moment to prevent fibrosis and to conserve function. None of the older methods of treatment will provide a clean, relatively sterile area for grafting purposes, and here again we realize the need for new methods. Under the occlusive treatment by plaster-of-Paris or adhesive tape, I find sterility is never reached, though the bacteriology may, after initial changes, become constant.



Your correspondents will have noted that I have said nothing about tannic acid. Perhaps it has its place in some burns in the first category, but even in this class experience leads me to believe that its potentialities for danger, if applied to the hands or face, are very great. If it is used for the second category of burns it cannot be expected to succeed, since it depends for its separation upon epithelial regeneration, which we know will not occur. The only alternative methods whereby it may be removed are either subjacent sepsis or surgical interference. One further point against its use is that most of us find ourselves quite incapable of deciding within the first few hours the exact degree of any burn. This is not evident for some days, and if tanning is to be delayed until that time most of its advantages will have been lost and it will be subject to the greater probability of subsequent sepsis.

So many divergent views have recently been expressed that it must be obvious that no ideal method of treatment for burns is yet available. At the beginning of the war opinions were more or less standardized but were based upon civilian injuries. Further experience and increasing knowledge lead me to believe that a satisfactory solution has yet to be found. I have hopes that this may not be long delayed, and in the meantime would suggest that only innocuous substances which will not vitiate any final treatment should be used for first-aid purposes.—I am, etc.,

London, W.1, April 22. RAINSFORD MOWLEM.

A Thomas Splint Modified to Braun's Type

SIR,—It was very interesting to read Mr. J. C. R. Hindenach's note (April 12, p. 558) on the use of a bent Thomas splint in lieu of a Braun splint for fractures of the tibia. Having used a Thomas splint instead of a Braun splint on these lines for the past two years I can fully recommend its merits. Not only is it an ideal form of splint for the treatment of fractures of the tibia requiring traction, but it can also be employed with advantage for those fractures of the femur in which the upper fragment is flexed and for which a Braun splint is usually advocated. This applies in particular to fractures of the upper third of the shaft. In the treatment of these the "bent" Thomas splint is an improvement on the Braun splint because when used with "fixed" traction (alone or combined with weight traction) it immobilizes the upper fragment and enables the patient to move his pelvis (for the

use of the bed-pan, etc.) without pain. This is not possible when a Braun splint is used, for in this case any movement of the trunk is accompanied by movement of the upper fragment since its immobility is dependent on weight traction only.

One modification of the Thomas splint should always be made when it is bent at the knee. The ring should be tilted on the bars so that its plane lies at right-angles to that of the bars below the knee (see diagram). This will obviate two things: (1) undue pressure on the groin which would other-

wise result from elevating the splint; and (2) tilting of the splint from pressure on the lower half of the ring. It is then not necessary to allow for the ring to sink into the bed as described by Mr. Hindenach.

Finally it needs to be emphasized that whenever a Thomas splint is used with "fixed" traction (apart from its use as a purely emergency measure) the ring should always be a good fit.—I am, etc.,

Liverpool, April 19. G. E. THOMAS, F.R.C.S., M.Ch.(Orth.)

Wound Healing

SIR,—Your important leading article on problems in wound healing (April 12, p. 560) draws attention to the point that at long last some surgeons are alive to the fact that it is necessary for them to consider their patients both medically as well as surgically. For the healing of wounds of all sorts we have to remember that all we can do is to help Nature in her work of repair. The healing process is dependent on the health of the body cells, especially in the neighbourhood of the wound, though it is difficult, if not wrong, to think of the possibility of some of the cells of the body being healthy and others unhealthy.

You kindly allowed me on April 5, 1906, and July 15, 1906, to point out the value of lime salts—calcium chloride in medical wounds such as ulcers, and calcium iodide for ulcers of the legs, and, still later, calcium permanganate for ulcers of the stomach. The value of calcium salts is now fully recognized, though when I first advocated their use I was thought to have lime on the brain. Strangely enough, even to-day the value of iodine combined with calcium as calcium iodide is still not recognized as it ought to be, although it is tasteless, non-depressing, and does not produce iodism.—I am, etc.,

Swansea, April 15. G. ARBOUR STEPHENS.

Milk in Wartime

SIR,—One factor which has favoured the recent improvement in the public health is in jeopardy—the increased use of liquid milk. In this last month of March this country consumed 63,000,000 gallons of liquid milk, a record figure since the Milk Marketing Board has been in the saddle. It is almost double the initial figure. Milk in school, milk for nursing mothers and expectant mothers, milk for young children, and, in a different category, the consumption of milk in milk bars and with the morning porridge have all contributed to this result. It cannot be doubted it is especially beneficial at this time when other sources of "good" protein are reduced.

Yet it is just at this time the Minister for Agriculture speaks of reducing the numbers of cattle in the country and of reducing each class of cattle proportionately. That is to say, it is suggested that in-calf heifers, and young cows in their first lactation, shall be reduced in proportion, as well as the veterans of a number of lactations. The reason for reduction, of course, is the diminished amounts of feeding stuffs imported. I would respectfully submit the following considerations as seeming to warrant a modification of this policy:

(1) The shortage of imported foodstuffs for cattle may prove, in the long run, an unalloyed blessing—that is, if our dairy farmers plough their grass, in their rotation, and grow their cattle feed as their forefathers did. There is a growing realization that all is not well with a system based on foreign feeding stuffs, and that disease, rampant when they are used, is negligible in herds fed on the produce of our own soil. I assume high tillage. Let me give an instance of what is possible. A large-scale dairy farmer, curtailed in his supplies, from the docks, of cake and so forth, ploughs up old park land with a doormat-like turf, turns it under, ploughing deep; and at the same time, to counter both acidity and wireworm, salts the land with 5 cwt. of salt per acre. Then he sows with oats and beans. What a magnificent crop results! How his cattle relish it! His neighbours, used to monoculture, have their eyes opened to the advantage of the Oriental system of mixed cropping. And the beans provide oil which we had almost come to think must be bought from abroad.

(2) Would it not be wiser to encourage some such policy and at the same time to make any reduction that must be made in the head of dairy stock in the older milch cows and such as are the subjects of doubt and anxiety? The late Prof. Delépine used to say that infection was conveyed by the older cows: even if the young had contracted disease, it had not had time to reach an infectious stage.

Anyhow, by all means, let us maintain the high supply and high popularity of liquid milk.—I am, etc.,

Holmes Chapel, April 21. LIONEL JAS. PICTON.

Discission of Secondary Cataract

SIR,—The value of an effective mydriatic in making the lens capsule taut, and therefore easing its discission, is rightly stressed by Mr. F. E. Preston (April 19, p. 609). But the one certain means of dealing with an elastic capsule, or any capsule for that matter, is the use of two Bowman's needles thus:

The patient lies on his back. The eye is anaesthetized. The speculum is inserted. The capsule is illuminated by a focal beam. The operator wears binocular magnifiers. He stands behind the patient's head. The eye is fixed by forceps at III on the clock face. One needle is pushed through the sclero-corneal margin at IX o'clock. The capsule is tested. If it be elastic the fixation forceps are put down and the eye held by the one needle only. Then the second needle is inserted at III o'clock. Both needle blades are now in the anterior chamber. The capsule can be held by one needle and cut or torn by the other; or it can be twisted and torn away from its adhesions by rotating one needle over the other. Good control means less pull upon the eye.—I am, etc.,

Crockham Hill, April 21 N. BISHOP HARMAN.

Continuous Pentothal Anaesthesia

SIR,—I have been interested in two recent letters on this subject, one by Dr. R. Hastings Moore (March 22, p. 462) and the other by Dr. Geoffrey Organe (April 5, p. 535). In view of these, and following two personal cases, I venture to offer a further letter on the subject.

1. *Fibrillation of Muscles.*—This is rarer with pentothal than with evipan, and may often be avoided by warming the fluid and allowing it to stand for two to five minutes before injecting. It also helps to avoid restlessness during induction and recovery.

2. *Sudden Muscular Contraction.*—This may occur in spite of muscular relaxation being present, and is more especially seen in vulvar, bladder, and perineal operations, stimuli from which evoke strong reflex responses.

3. *Very Shallow Breathing and Cyanosis.*—I strongly endorse all these authors have to say concerning inexperience in the use of these drugs, and in the measures which should be at hand for resuscitation. My two cases will help to stress this point.

4. *Persistent Coughing.*—I have found that over-rapid injection with the presence of mucus in the pharynx often causes this. The value of premedication is well seen here. I am aware that others say that too slow an injection is the cause of these symptoms and of parasympathetic overactivity—namely, coughing, sneezing, and hiccup. I agree with Dr Organe in saying that in these cases the injection is better discontinued after 1 gramme (20 c.cm. 5% solution) has been injected, and the subject considered unsatisfactory for this form of anaesthesia.

5. *Severe Laryngeal Spasm.*—This is undoubtedly the result of a surgical stimulus which has evoked a reflex response in the presence of too light a level of anaesthesia. It is closely related to point 2. Stretching the anal sphincter requires a deep level of anaesthesia, and for this reason I consider most cases of "haemorrhoids" are unsuitable for pentothal. A spinal anaesthetic is pre-eminent in this sphere of surgery. Except for out-patients and the aged, I always favour light premedication before injecting these quick-acting barbiturates.

Case 1.—This occurred soon after I had qualified. I was asked to anaesthetize an old cachectic man of 70 for the removal of radium needles from the throat. Recalling the original estimation of dosage for evipan, I injected 1 c.cm. every fifteen seconds until consciousness was lost. Observing this quantity to be about 5 c.cm., I forthwith injected the remaining 5 c.cm. Following the removal of the needles I was horrified to find the patient black in the face and not

breathing. Fortunately his heart and circulation remained active, so that artificial respiration, intratracheal O_2 and CO_2, and intravenous coramine saved him. This lesson happily occurred early enough for me to realize the dangers of this technique and to study closely the indications and contra-indications for the drug.

Case 2.—Here I was an onlooker. A house-surgeon employed the above method of dosage for excision of a papilloma on the chin of an anxious man of 68 admitted direct to the theatre from "out-patients." Here respiration ceased following marked uncorrected cyanosis, and was followed soon after by cessation of the heart beat. All the above resuscitative measures, as well as intracardiac puncture and cardiac massage, proved unavailing. It may be stressed here that intravenous coramine is a waste of time in the absence of a heart beat. Nothing short of intracardiac puncture with subsequent cardiac massage and continuous endotracheal oxygen with artificial respiration will be of any avail.

In view of these two cases it is important to read carefully the full literature as supplied by the makers of these barbiturates, or that found in the textbooks, and not to rely solely on the small paper pamphlets which can be found inside the cartons containing the ampoules. It is a regrettable misfortune when a fatality occurs to an out-patient or for a very minor operation. Regarding these two cases, I am aware that both failed to do justice to a recognized technique of dosage.

The "biological" dosage scheme was introduced by Lauber. Maintaining a constant rate of injection, the patient is made to count, and thus the moment is noted when consciousness is lost. Then if the patient is young and strong, as much again is injected for short operations, and twice as much for a long operation. If the patient is old or cachectic then half as much again is injected for short operations or one and a half times as much for a longer operation.

This clearly indicates that in the two cases reported this method was misused, and therein lies the danger. A method such as this may be misunderstood, or one of its points not correctly grasped, by the anaesthetist. The result is totally unfair to the drug and serves to bring it or the entire group of short-acting barbiturates into undeserved disrepute. It is better to gauge the dose *during* the injection by careful observation of the patient.

Concerning the safety factor of these drugs, an early investigation of 6,500 cases showed eight deaths, a mortality of 0.123%; another series of 20,000 gave twenty-two deaths, a mortality of 0.11%. Although figures may be misleading, this is alarmingly high, and is probably due to over-rapid injection—misuse of method—and poor selection of patients.[1] My reason for recording these two cases is simply to warn the inexperienced or over-confident of the unforeseen dangers which lie in the administration of these drugs. These dangers lie in the extreme ease with which they are injected and produce their results.

The question, "How long does pentothal last?" or "How much shall I give?" requires a very careful answer, depending on a number of conditions. The dosage for each case must be considered individually and due modification made according to circumstances. This is true for the controllable inhalation anaesthetics. How much more true, then, for the so-called "uncontrollable" anaesthetics? The recognition of these conditions and the administration of the appropriate dose constitute the art of the anaesthetist. There can be no rule of thumb to be adhered to in every case. The dose is dependent on the metabolic rate; the age, sex, and weight of the patient; the type and extent of the proposed operation; and the presence or absence of premedication.

With the old method of dosage it is easy to administer an overdose to a debilitated subject without realizing it for a little while. The circulation is slow and depressed and the signs of anaesthesia are delayed. The additional amount may prove to be just double the minimum dose required for the operation. For very short minor operations in healthy subjects adequate anaesthesia is obtained by injecting 5 or 6 c.cm. (0.3 gramme 5%) of pentothal rapidly. This gives time for a tooth extraction or for an incision and drainage. The anaesthesia is transient and deep. Twice this dose in the same patient given slowly over two to three minutes might not even produce unconsciousness. For longer cases the technique which appeals to me, and which I have used without a fatality in 250 cases, is similar to that described by Prof. Macintosh.[2] Estimation of dosage and minute-to-minute control are carried out during the injection by very careful observation of the patient. The mind must not be allowed to concentrate solely upon the barrel of the syringe. The patient has to be watched for loss of consciousness, cyanosis, and relaxation; finally, the site of injection must be observed to avoid extravenous deposition of fluid. Two to three c.cm. is injected in ten to fifteen seconds, followed by a thirty-second safety pause to watch the effects. Further quantities are then injected, having regard to the various conditions mentioned above. Usually I give a further 3 or 4 c.cm. in half to one minute.

Unconsciousness supervenes during, or at the end of, the first safety pause, and relaxation occurs generally after two minutes have elapsed from the start of the injection. The surgeon should be asked not to make any preparation or incision until the full two minutes have elapsed. This will avoid a sudden momentary jerk or even continued restlessness during the operation. The presence of surgical anaesthesia is judged not by the rate but by the shallowness of the respiration. Providing safety pauses are made further quantities are injected, and 1/2 to 1 c.cm. every five to ten minutes is all that is necessary to maintain even anaesthesia. These safety pauses are highly important, and constitute the method of control of dosage as well as obviating any dangers that may arise from retarded circulation or extravenous injection.

These drugs are best given in the recumbent posture and not in the sitting or reversed Trendelenburg positions.—I am, etc.,

Successful Adrenal Graft in Addison's Disease

SIR,—I think most clinicians would hesitate to regard any case of Addison's disease as "indisputable," particularly when, as in the case reported by Drs. Katz and Mainzer (April 26, p. 617), there was no pigmentation either in the mouth or elsewhere, and the symptoms had been present for ten years or more.

Low blood pressures, by which I mean a systolic pressure under 100 mm. Hg, are not very uncommon even in healthy adults, and occur much more often in the asthenic type of invalid described by the authors. Without wishing to stress in any way the value of laboratory findings in the diagnosis of Addison's disease, there does not appear to be any evidence from biochemical investigations to support the diagnosis. Possibly a better title for the paper would have been "Grafting of Adrenal Gland in a Case of Suspected Addison's Disease."—I am, etc.,

J. J. CONYBEARE.

London, S.E.1, April 28.

Acute Abdominal Pain after Opium Medication

SIR,—Mr. H. P. Winsbury-White, in his letter under the above heading (March 22, p. 461), asks for other practitioners' experiences, and I venture to report a case which occurred last week. A man of 35 with a comminuted fracture of the leg was given morphine sulphate 1/4 grain hypodermically, and within ten minutes he was seized with violent colicky abdominal pains. He writhed about in bed; he resented palpation of the epigastrium; and I could not help wondering if he had a perforation. There was no vomiting, and the pain passed off in about an hour.

Case No. 4 in Mr. Winsbury-White's series was relieved by atropine; but the case here reported had already received 1/100 grain of the latter drug some twenty minutes previously in anticipation of a general anaesthetic. The dosage of morphine here was not large. Had I not seen Mr. Winsbury-White's letter I should have been even more puzzled at the onset of pain after morphine than I actually was.—I am, etc.,

E. MARCUS LIDDLE.

Crewe, Feb. 15.

Vitamin B_1 in Diphtheria

SIR,—We have read with interest Dr. Hugh Climie's letter (April 12, p. 572) on vitamin B_1 in diphtheria. We suggest that his cases are of very doubtful value in the elucidation of the value of vitamin B_1 in diphtheria, especially as he apparently has not checked his results by controls.

He states that "there would appear to be need for further investigation into this subject, but the use of vitamin B_1 in cases of severe diphtheria would seem justifiable to ensure complete oxidation of the large quantities of glucose usually given to such cases." We would like to bring to Dr. Climie's notice the following. Prof. Peters and his colleagues have shown that vitamin B_1 is important in the later oxidation changes of glucose, and if this vitamin was deficient an increase of pyruvic acid could be demonstrated in the tissues of the blood of experimental animals. Peters and Cunningham[1] carried out a series of analyses on normal guinea-pigs bled to death. Another series of guinea-pigs were inoculated with four minimum lethal doses of diphtheria toxin and estimations of pyruvic acid were made on the blood taken shortly before death. The figures for the injected animals showed no appreciable deviation from the normal figures. They then attempted to produce the chronic form of the disease by injecting toxin and later concentrated antitoxin. Their results on these animals also showed no significant deviation from the normal. The muscles of some of both the normal and the injected animals were tested qualitatively for pyruvate, the reaction was always negative, except in one or two isolated cases. They followed up their animal experiments by clinical ones and demonstrated that the percentage of pyruvic acid in the blood of two severe cases of diphtheria suffering from paralytic sequelae showed no considerable alteration from the normal. These two workers concluded their article with the statement that "it is thus obvious from the experimental and clinical results that the stage of glycolysis in which vitamin B_1 is concerned is not affected by the diphtheria toxin, and no benefit arises in this condition from its administration."—We are, etc.,

The Royal Infirmary, Worcester.

April 21.

Cause of Appendicitis

SIR,—I have only just seen the letter of Dr. J. Price Williams (November 2, 1940, p. 612). He notes that appendicitis is a disease characteristic of the last half-century, and while he rejects the idea that it is due to meat-eating, he implies by his reference to castor oil that constipation is an important factor in its causation. It is interesting to note in this respect that around 1890 white bread came into general use, and as a result the average daily intake of vitamin B_1 in England fell from about 1,000 I.U. (from all foods eaten) to 300 I.U.[2] The minimum daily intake for health is estimated at from 300 to 600 I.U.,[3] while 646 has been recommended.[4] Animal experiments suggest that a deficiency results in diminished tone of the non-striped muscle of the intestine, and a supplement of B_1 has been recommended in the treatment of constipation.[5] The retention of faecal matter in the caecum, assisted by gravity, would seem to provide the ideal condition for the development of appendicitis, especially if there is atonia. If this is so, beriberi should be associated with a high incidence of appendicitis, other things being equal. But they are not. The beriberi of rice-eating countries occurs where consumption of meat and other foods liable to rapid putrefaction is relatively very small.

The likelihood that appendicitis is largely due to the combination of a critically low intake of vitamin B_1 and a fairly large amount of animal protein and too little "bulk" seems sufficient to justify investigation. If steps are taken to ensure adequate supplies of B_1 in the nation's diet by encouraging the widespread use of wholemeal flour, or at least the fortified loaf, together with the effect of meat rationing, it is possible that the number of appendicitis cases may fall significantly. It would be interesting to know if any figures are available.—I am, etc.,

St Andrews, April 16. F. L. ROBERTSHAW.

SIR,—Your excellent *Journal* is of necessity read in this remote place some months after publication. In your issue of October 12, 1940 (p. 505), I read with growing consternation a letter on the cause of appendicitis by Dr. Josiah Oldfield. That such treatment is practised and such views held in these enlightened times is to my way of thinking little short of astonishing. Admittedly many reputable surgeons still administer large doses of anti-gas-gangrene serum in cases of acute appendicitis complicated by rupture, but I have yet to see this application of Dr. Oldfield's theory do any good.

One agrees with Dr. J. Price Williams (September 14, 1940, p. 367) that the cause of appendicitis is trauma, but surely the trauma is not always *in the cradle. If Dr. Oldfield took the* trouble to brush up his anatomy he would find that the appendix, in respect of its blood supply, is divided into thirds, and that at operation any of these thirds may even be gangrenous while the other two appear quite normal: surely the steak was not just one-third bad which in its caecal putrefaction caused this catastrophe. Again, how does he explain the acute appendicitis which occasionally complicates enteritis, when the passage of food through the intestine is often distressingly rapid? Appendical pain is not always caused by appendicitis: only to-day I removed an appendix which had caused its owner severe pain, and yet it was normal except that it contained a coprolith—obviously a case of appendical colic comparable to that caused by a stone in the ureter.

Every case I see convinces me that the cause of appendicitis is traumatic, inasmuch as the trauma is to the blood vessels, first causing engorgement, by venous interference, and oedema (the white stiff appendix) and later anaemia, by arterial interference, and gangrene. At this point the organisms from the much-maligned caecum begin their invasion. When one argues why this vascular trauma should occur deeper waters are reached. Far be it from me to state that diet, and with it more or less habitual constipation, have no part—most probably they are the exciting cause of the trauma by interfering with the relative position of the meso-appendix.

Dr. Oldfield's treatment with its enemata, long fasting, and castor oil is even more drastic and uncomfortable than an operation with little or no disturbance of the other abdominal viscera. In this country we favour the muscle-splitting incision, and the resulting harm to the abdominal wall is practically *nil*. I am neither a long-intestined frugivore nor a short-intestined carnivore, but Heaven preserve me from a colectomy so that I can exist on modern food.—I am, etc.,

Darwin, N.T., Australia, Jan. 9. C. LELEL.

"Heat Convulsion"

SIR,—The following case of "heat convulsion" may be of interest to some of your readers, as it presents a number of unusual features.

A male aged 18 was admitted to hospital with an acute osteomyelitis of the left tibia. He had a temperature of 104.6° F. and a pulse of 80. His general condition was good. Operation was decided upon, and I ordered 1/4 grain of morphine pre-operatively. Anaesthesia was induced with gas-and-oxygen, using a Coxeter apparatus and employing partial rebreathing from the outset. No ether was given at any stage. At the beginning of induction he became a shade cyanosed, but this was rapidly relieved as anaesthesia became well established; at no other time did cyanosis occur. He was perspiring very freely and secreting copious quantities of saliva, which poured from his nose and mouth. In an effort to control this fluid loss he was given 1/50 grain of atropine. The operation had been in progress only about twenty minutes when I noticed twitching of his facial muscles, accompanied by clonic movements of the arms and legs, which had to be held down by the theatre-room staff. The theatre was hot (80° F.); the patient's temperature had risen to 105° F. and his pulse to 180, while his respirations became irregular. Pus

had been located and the tibia was about to be trephined. A Phillips airway was inserted and 6 litres of oxygen with 1 litre of carbon dioxide per minute was administered in an effort to regulate his breathing. As the continued administration of this mixture had little effect in arresting the development of the convulsion I thought it desirable to give a few c.cm. of pentothal. The convulsion began to wane after only 2 c.cm. had been injected, and had entirely ceased with 4 c.cm. The operation was continued for about another thirty minutes; but there were no further convulsions in the theatre or subsequently in the ward, neither did his condition give rise to any anxiety. On being returned to bed he was given a rectal saline, followed by a continuous intravenous drip saline.

The interesting features about this case are: (*a*) it resembled very closely the so-called "ether convulsion," yet at no time was ether administered; (*b*) the convulsion developed shortly after giving a large dose of atropine; (*c*) the patient's temperature was very high, he was toxic, and in addition the theatre was hot, ventilation being almost non-existent owing to the black-out; (*d*) the operation had been in progress only a short time, the patient was inclined to be lightly under, and his colour was good; (*e*) oxygen and carbon dioxide had little effect in arresting the condition, which was readily stopped with a small dose of pentothal.

In my opinion this was a heat convulsion entirely due to hyperpyrexia aggravated possibly by the heat of the theatre plus the toxic condition of the patient.

I am indebted to Wing Commander R. Thorpe, senior medical officer on the station, for permission to publish this case.—I am, etc.,

March 26. S. E. OSBORNE.

Medical Planning Commission

SIR,—If the views expressed in the letter from Dr. Genge printed in your issue of April 19 were his alone it were best ignored and left to a speedy and a kindly oblivion. But his letter is written on behalf of the Medical and Panel Committee of an important county borough, and if we are to believe that these are the considered opinions of a representative group of general practitioners, then indeed mischief is afoot.

It is common ground that doctors wish to place their skill at the service of their fellows and that they wish to do so under reasonable conditions, both financial and administrative. It is common ground that the present confusion in the medical services of the country causes grave dissatisfaction in our profession and robs the community of service urgently needed.

Most of us look to the Medical Planning Commission to make proposals the effect of which would be to unite the profession in rendering improved service to the community. But not so Dr. Genge. Myopia and delusions of persecution unhappily combine to make him wish to fling the general practitioners into a war on three fronts—against medical officers of health exercising insufferable powers, against consultants casting envious glances, and against a third foe not so clearly defined who is to be overthrown by loud shouting. So impatient is Dr. Genge for the battle to begin that he cannot wait to hear what the Commission has to propose. So intent is he on victory that he does not pause to consider that in such a war the good name of our profession and the service of the public would both be casualties. It is a sad case occurring in a localized epidemic. Prompt reflection should prevent spread.—I am, etc.,

Potters Bar, April 23 MAITLAND RADFORD.

SIR,—Criticism levelled against the Medical Planning Commission has been the consequence of lack of information, and the feeling of misgiving much lessened by the timely letter of Mr H. S. Souttar (April 12, p. 569). Had it been written at the time of the announcement of the Commission one would have felt that, although the Executive was acting within its rights constitutionally, the terms of reference were not quite so purposeless as at first appeared to be the case. For surely the terms of reference are quite contrary to the purpose of the Commission as implied by its name, Medical *Planning* Commission.

The Commission as constituted, with facilities at its disposal for comprehensive inquiry, is quite capable of discovering why medical reforms are necessary. Further, from a review of the situation in this and other countries, and of methods of reform previously suggested, practicable alternative proposals for future adoption may be made. But in what respect is this inquiry made necessary by the circumstance of war?

I suggest that this is the proper limit of the scope of the Commission. Therefore it would be well for the Commission, at its first session, to make an authoritative announcement upon its interpretation of the terms of reference. Precision in this respect will ensure a happy environment so far as that is dependent upon the good will of the profession in general.—I am, etc.,

MAURICE WIGFIELD.

Watton-at-Stone, near Hertford, April 26.

Medical Man-power

SIR,—We have heard a great deal lately about the acute shortage of medical personnel. Will anyone courageously publish the facts? For when the facts and the truth are published there is evidence of maldistribution, muddle, and rapacity.

The G.M.C. informed me a year ago that the number on the *Medical Register* was approximately 64,500; this included aged, infirm, retired, and women practitioners. Recently qualified will make this number up to (allowing for death) about 65,500. Of these, I understand, approximately 36,000 are normally engaged in practice in England and Wales. The Services (by which we really mean the Army, as the Navy and Air Force are small numerically in comparison) would like to have, apparently, about one medical officer to every 250 fit and healthy young men; hence for 3,000,000 about 8,000 to 12,000 medical officers, the remaining 42 millions of population being left with the balance, about 24,000 to 28,000 medical practitioners, for all the other services—civil, general practice, consultant, E.M.S., and so on!

Approximately half the Army medical officers are engaged in administrative, clerical, and office duties; the other half who are doing clinical work (so-called), for the most part in the United Kingdom, only treat minor maladies, all serious cases being transported to the local hospitals in their districts. Hence this horde of Army medical officers are not even dealing with, nor have they in many instances the equipment with which to treat, anything like all their cases. At home the Army is rapacious, desiring the lion's share of the nation's limited medical personnel, and having taken these thousands of medical men, for the most part at £450 per annum in a rank and status equivalent to that of a sub-lieutenant R.N., aged 20 years, they do not even do their own work!

It is obvious where combing is required. In many areas general practitioners are being worked to death. What has happened to the thousands of consultants and general practitioners from denuded areas, whose practices have virtually disappeared?—I am, etc.,

CHARLES A. H. FRANKLYN, M.D., M.R.C.S.

Oxford, April 14

Malarial Therapy for Epilepsy

SIR,—In view of Dr. G. de M. Rudolf's letter (April 26, p. 647) and your annotation on the treatment of G.P.I. (March 29, p. 486), the following extract from Dr. O. C. Gruner's translation, para. 228, p. 171, of "The Canon of Medicine" (Avicenna, A.D. 980–1037) might prove of interest:

"Some diseases turn into new ones and so themselves disappear. This is very satisfactory. One disease becomes the medicament for curing another. Thus quartan malaria often cures epilepsy (cf. G.P.I.), also podagra, barices and arthralgias. A spasmodic disease may be cured by scabies, pruritus and furunculosis. A certain type of diarrhoea is cured by inflammation of the eyes. Lienteria cures pleurisy. Bleeding piles removes atrabilious disorders, including sciatica, renal and uterine pain. But the passage from one disease to another may be a serious matter; for instance, when an empyema spreads into the substance of the lung and when meningitis becomes lethargia."

Dr. Rudolf, in his book, mentions the Hippocratic reference to the effect of malaria on epilepsy.—I am, etc.,

M. B. RAY.

London, W.1, April 26.

The "English Disease"

SIR,—In Dr. H. M. Raven's letter (*Journal*, April 19, p. 606) there appears a remark that, though it is not strictly germane to the current controversy about calcium requirements, I should like to be allowed to correct, because it is frequently met.

Rickets was not called the "English disease" because it was particularly characteristic of English children, but because in 1650 Francis Glisson, then holding a Cambridge chair, published the first detailed and accurate description of the disease. From this it derived on the Continent of Europe the appellation quoted by Dr. Raven, but given by him, as by so many other writers, an incorrect and misleading interpretation that is unfair even to our curious climate.—I am, etc.,

Greenford, Middlesex, April 22. A. L. BACHARACH.

Obituary

F. GRIFFITH, M.B., and W. M. SCOTT, M.D

Medical Officers, Ministry of Health

The scientific staff of the Ministry of Health suffered a severe loss last month when Dr. Frederick Griffith and Dr. William McDonald Scott were killed by enemy action. They had long worked together in the Ministry's laboratory in London, and their reputation as bacteriologists was very high.

Dr. Griffith, younger brother of the late Arthur Stanley Griffith, M.D., of whom Sir Arthur MacNalty wrote an appreciation in last week's *Journal*, received his medical training at University College, Liverpool, graduating M.B., Ch.B. of the Victoria University in 1901; he took the D.P.H. of Oxford in 1910. After serving as house-physician and house-surgeon at the Royal Infirmary, Liverpool, he worked in that city as Alexander Fellow in Pathology at the Thompson Yates Laboratory, a post formerly held by his brother, and the two were associated as scientific investigators under the Royal Commission on Tuberculosis, carrying out researches of the first importance. Frederick Griffith was a member of Gray's Inn, and for many years past had been a medical officer of the Local Government Board and later of the Ministry of Health, working in the pathological laboratories from 1911 onwards.

Dr. McDonald Scott was an Edinburgh student, graduating M.B., Ch.B. with first-class honours in 1905, B.Sc. (Public Health) in 1907, and M.D. in 1910; he took the D.T.M. & H. in 1906. He held the Ettles scholarship at the University of Edinburgh, and afterwards the John Lucas Walker studentship in pathology at Cambridge, where he was for some years university demonstrator in pathology. Before joining the laboratory staff of the Local Government Board he had been a medical officer in the Straits Settlements Medical Service. On the establishment of the Ministry of Health in 1920 he became one of its medical officers. McDonald Scott was the author of articles on bacteriology and immunity in the *Encyclopaedia Medica*, and on influenza and anaphylaxis in the Medical Research Council's *System of Bacteriology*. He also wrote an important report in 1916 on meningococci occurring in the spinal fluid and similar micro-organisms in the nasopharynx.

S. GILBERT SCOTT, M.R.C.S., D.M.R.E.

Consulting Radiologist, the London Hospital

We regret to announce the death on April 19 at his home in Bourne End of Dr. Sebastian Gilbert Scott, for many years director of the radiological department at the London Hospital and radiologist to the National Hospital for Diseases of the Chest, and latterly honorary radiologist to the British Red Cross Clinic for the Treatment of Rheumatism. He belonged to a family that has produced famous architects and good doctors: his grandfather was Sir George Gilbert Scott, R.A., his younger brother is Sir Giles Gilbert Scott, R.A.

He was born at Hampstead on January 31, 1879, and was educated at Beaumont College, Windsor, and King's College, London, qualifying M.R.C.S., L.R.C.P. in 1904. After serving as house-surgeon at King's College Hospital and house-physician at the Royal Free Hospital he took up *x*-ray practice and returned to King's, working there as clinical assistant in the electrical department until his appointment to the post of radiologist at the London Hospital in 1909.

During the last war Gilbert Scott was radiologist to the Princess Beatrice Hospital for Officers, the Palace Green Officers' Hospital, and the Military Hospital at Broadstairs. After the war he was appointed consulting radiologist to Queen Alexandra's Military Hospital, Millbank, and a member of the Army *X*-ray Committee. He was a past-president of the Electrotherapeutic Section of the Royal Society of Medicine and held office in the British Medical Association as president of the Section of Radiology and Electrology in 1923, as chairman of the Westminster and Holborn Division 1932–3, and as a member of the Committee on the Causes and Treatment of Arthritis. He took the D.M.R.E. at Cambridge in 1921 and afterwards examined for that diploma. He published many papers on radiological subjects in this and other journals: his *Atlas of Chronic Rheumatic Arthritis (the Hand)* appeared in 1935 and his *Radiology in Relation to Medical Jurisprudence* in 1931. During recent years he took much practical interest in the work of the Charterhouse Rheumatism Clinic and in wide field *x*-ray research under a benefaction from Lord Nuffield.

JOHN SMYTH MACDONALD, F.R.S.

SIR ARTHUR HALL writes:

I should like to add to your recent obituary notice a personal tribute, not only to the work of Macdonald as a physiologist whilst in Sheffield but also to the important part he took in helping us to obtain a Charter for the University. When he was appointed as professor of physiology in 1903 we were still but a University College. The three Colleges of Victoria University had but recently dissolved partnership. Liverpool had already obtained a separate Charter, Leeds was applying for one. With this the recent hopes that Sheffield might one day join Victoria University as a fourth constituent had vanished. To those who had set their hearts on University status for Sheffield Macdonald was a great stimulus. Coming to us direct from Liverpool he was not only familiar himself with the procedure necessary in applying for a Charter but was able to secure for us the personal co-operation of those of his former colleagues and friends who had recently gone through it themselves. The University of Sheffield owes much to his and their help and guidance in those early days. He was entirely responsible for planning the Physiology Department in the University buildings, a department which at that time was one of the best in the country. Besides being the first to hold the chair of physiology in the University, he was Dean of the Faculty of Medicine for several years until he left us in 1914 to succeed Sherrington at Liverpool.

Dr. E. FRETSON SKINNER, an old student of Prof. Macdonald's, sends the following personal tribute:

The physiology department of the Sheffield Medical School, as it then was, and of which he had charge, had an atmosphere of workaday enthusiasm that was stimulating to a degree, and every student who passed through Macdonald's hands must have absorbed and carried away something of his exuberant vitality and purposefulness. He had a true simplicity and kindliness of character, and I never heard him say an unjust or even an unkind word of anyone, not even of one who had done him a grievous hurt. Whatever subject he discussed he brought to it an original touch, and even the simplest routine laboratory experiments under his hands were made to have a real meaning for us. He had a boundless enthusiasm and made those who worked with him participants in it. He would devote hours or days to a single experimental detail, and though keen to fit it into a system of ideas, if it worked

out wrongly he would unhesitatingly discard it and start afresh. Besides possessing a friendliness that endeared him to his juniors, Macdonald was a real teacher. Among other efforts he made to cultivate interest in his classes was that of asking senior students to take a special item in a subject, read it up, and then deliver a lecture to their class-mates. It was indeed a novel idea and could only have succeeded under one who inspired enthusiasm, but it was enjoyed and appreciated by the class. The Sheffield Medical School and the Medical Faculty of the University owe much to his *enthusiasm and originality.*

"C. M. S." writes: In the obituary notice of Dr. DAVID FORSYTH your correspondent "M.B." says that hospital work afforded no scope for the psycho-analytic therapy in which he excelled. With this one cannot disagree, but it should be amplified to the extent that his hospital work certainly enabled him to treat most successfully the milder cases of neurosis that were often admitted to his wards. And, what is possibly of equal importance, those of us who had the privilege of serving Forsyth as house-physicians were given a lasting sympathy with those unfortunately grouped as neurotics—and an ever-increasing understanding of the vital importance of psychology. Forsyth was blessed with great gifts, among them a highly developed clinical sense. Although for many years his main interests were psychological, he kept fully abreast of modern developments in medicine, and gave every encouragement to his H.P.s to try out any new treatment. His ward rounds attracted large numbers of students and his bedside teaching was noteworthy for clarity of expression. We shall miss him for many things, but above all perhaps for his never-failing urbanity and sympathetic hearing of any difficulty, professional or personal.

It is with regret that we note the death of Dr. BERKELEY ROBERTSON, after a short illness, on April 13. Dr. Robertson, who was 60 years of age, was born in Glasgow, educated at Glasgow Academy and Glasgow University, where he graduated in Arts and Science before taking his medical course. He graduated M.B., Ch.B. with commendation in 1904, and then spent a year in house-surgeonships in the Royal and the Western Infirmaries. He belonged to a family noted in Glasgow for its great interest in the Church and in foreign missions, and it seemed natural that he should determine upon medical missions as his life's work. He was appointed to Livingstonia Mission, where he gave notable service in ophthalmology as well as in the other departments of that great mission station. After three and a half years, however, anxiety for his health demanded return home and he was advised to relinquish service in Africa. He settled in practice in the west end of Glasgow and became a noted and esteemed family doctor. In 1912 he took the D.P.H. of Cambridge, and in 1919 he graduated M.D. in Glasgow. Dr. Robertson was of a genial happy disposition, greatly liked by his patients and by his fellow practitioners. A keen Churchman, he took great interest in Church affairs, especially in relation to foreign missions, and was a conscientious member of Session in his own church and a knowledgeable representative of the Livingstonia Mission in the General Assembly. He had a cultured mind, and was well read in theology, philosophy, and poetry. Much sympathy is felt with Mrs. Robertson and her family, one of whom, her son, is beginning the study of medicine at the University of Glasgow.

Dr. GORDON STEWART WOODMAN, who died suddenly on April 15 at Llandudno, was born at Haltwhistle-on-Tyne on January 12, 1891, and was educated at Dollar Institution and the Medical College of Durham University at Newcastle. He graduated M.B., B.S. in 1913 and took the F.R.C.S.Ed. in 1920. At Newcastle he was house-surgeon and junior resident medical officer at the Royal Victoria Infirmary, and then served in India and Mesopotamia with a temporary commission in the R.A.M.C. After the armistice he was civil surgeon at Iraq for a year and then surgical specialist to the new general hospital at Baghdad and surgeon to the Iraq Petroleum Company. For a time he was also director of the surgical unit and professor of clinical surgery at the Royal Hospital, Baghdad. Returning to this country he settled in general practice at Llandudno, and was appointed gynaecologist to the Llandudno District Hospital and the Heroes Memorial Hospital at Blaenau-Festiniog. Dr. Woodman joined the B.M.A. in 1920 and had been honorary secretary of the Mesopotamia Branch, which he represented at the Annual Representative Meetings of 1926 and 1930.

Dr. THOMAS LEATHARD WORMALD, medical officer since 1920 to the Darlington Rural Council, died on April 14. He was born at Prudhoe-on-Tyne on March 9, 1885, and was educated at Darlington and Newcastle, graduating in medicine at the University of Durham in 1906; he took the B.Hy. degree and D.P.H. in 1909, and the M.D. in 1910. Dr. Wormald was the first full-time medical officer to be appointed by the old Darlington Board of Guardians; this was in 1911, after he had been senior assistant medical officer to the Newcastle-on-Tyne workhouse infirmary for three years. During the last war he served with the R.A.M.C. in France at No. 6 General Hospital, in a field ambulance, and as battalion M.O. For the past ten years he had been obstetric physician to the Darlington General Hospital. He joined the British Medical Association in 1909.

News has been received of the death through enemy action of Dr. PETER RUSSELL CAIRNS and his wife, of Southport. Dr. Cairns, a native of Galashiels, was educated at the Old Galashiels Academy and the University of Edinburgh. He qualified L.R.C.P. & S.Ed. and L.R.F.P.S.Glasg. in 1893. For a number of years he was in practice at Southport in partnership with his brother, Dr. Lawson Cairns, and retired from active work some ten years ago. He had been a member of the British Medical Association from 1896 until the time of his retirement.

The following well-known medical practitioners have died abroad: Dr. G. E. VINCENT, president of the University of Minnesota, 1911–17, and of the Rockefeller Foundation in New York, 1917–29, aged 76; Prof. CARLOS G. MALBRAN, the first occupant of the chair of bacteriology at Buenos Aires University; Dr. PEDRO OVIDIO BOLO, vice-president of the Academy of Surgery, of Buenos Aires; Dr. DAVID RIESMAN, formerly professor of clinical medicine in the University of Pennsylvania, and a prolific writer on pathology, medicine, and medical history, aged 73; Dr. EUGEN ENDERLEN, successively professor of surgery at Basle, Würzburg, and Heidelberg, aged 67; Dr. KATE CAMPBELL MEAD, born in Quebec, author of *A History of Women in Medicine*, and formerly president of the International Association of Medical Women, aged 73; Dr. WILLIAM MILES WISHARD, sen., emeritus professor of genito-urinary surgery at the Indiana University School of Medicine, aged 89; Dr. LUDWIG MAYER of Heidelberg, author of works on hypnosis and psychotherapy, aged 48; Dr. HANS GUDDEN, formerly director of the Munich Psychiatric Clinic, aged 73; Dr. CHARLES V. CHAPIN, an eminent epidemiologist who was for forty-seven years medical officer of health for the city of Providence, aged 85.

We are asked to correct the obituary notice of the late Dr. ERIC SNELL which appeared last week (p. 655) by adding that his younger son, Flying Officer E. Peter S. Snell, is also following in the medical tradition of the family and has been a medical officer in the R.A.F.V.R. since last summer.

The annual report of Crichton Royal Institution, Dumfries—the one hundred and first—gives the number of patients under treatment at the close of the year as 1,043, of whom 675 were private. In addition there were 141 patients who had been evacuated from Edinburgh Mental Hospital. The physician-superintendent, Dr. P. K. McCowan, says that among the new admissions it is noteworthy in how few the breakdown can be traced to the war and its attendant anxieties. The reaction of the hospital population to the war varies according to their mental condition. A certain number are so much out of touch with reality that the war means nothing to them, a few weave delusional ideas around it, while the remainder regard it with the same mixture of intelligence and ignorance as the general population. Two cases of schizophrenia following head injury have been treated with insulin at the institution. Both patients seemed doomed to a life of chronic mental invalidism, and both are now living useful lives in the outside community. In another case of schizophrenia electrical shock treatment and detoxication by surgical means, supplemented by occupation, recreation, and psychotherapy, brought about a recovery which would not have been attained by any of these means alone.

Medico-Legal

WRONGFUL DEDUCTION OF PANEL FEES

An insurance practitioner recently succeeded in an action against a county insurance committee for the payment of a sum which had been deducted unlawfully from his capitation fees. Before the deputy judge at Windsor County Court, Dr. H. Tudor Edmunds, of Slough, sued the Bucks Insurance Committee for £3 13s.[1] A satisfied patient, the manager of a firm in business outside the doctor's district, telephoned to the doctor to call and see three of the firm's employees who were ill. He did so, and no one told him they were insured persons. About a week afterwards, when making the entry in his daybook, this possibility entered his mind and he reduced his fees by a half, as he thought the patients might have to contribute some payment to the firm. It appeared later that two of them were insured persons. The firm paid his bill, but afterwards asked him to refund £3 13s., his charge in respect of the two insured persons. The insurance committee without hearing the doctor, deducted this amount from his panel payments. Counsel for the committee suggested to the doctor when he gave evidence that, if he had known that these persons were insured and had treated them as such, he could not have expected a fee from the firm. He replied that a doctor was often called in to deal with the employees of a firm, rather than that the firm should each time summon the panel doctor of a sick employee. He was employed by two firms at Slough whose employees he treated for payment whether they were insured persons or not. Counsel submitted that the judge had no jurisdiction in this matter, because the committee was a semi-judicial body and the question was dealt with in the Medical Benefit Regulations. The judge held that he had jurisdiction. Giving judgment, he said the committee was not entitled to deduct this sum, for the contract under which the doctor was employed was with the firm and not with the insured persons. The patients did not pay, and they were not therefore entitled to recover or to ask the committee to refund the fee. It seemed to him a pity—as, in fact, counsel had admitted—that the committee had not dealt with the doctor more as a professional man should have been dealt with, and at least have heard what he had to say. If they set themselves up as a judicial body, nothing more unjudicial could have taken place. He gave judgment in favour of the doctor for the amount, with costs on the highest scale, in view of the importance of the case to the medical profession and insurance committees.

[1] *Windsor, Slough and Eton Express*, Feb. 7.

STATISTICS OF INFANTICIDE

In a paper read to the Medico-Legal Society Dr. J. C. Matheson, governor and medical officer of Holloway Prison, gave some interesting statistics with regard to infanticide. During the period of five years 1936–40 eighty-one women were admitted into Holloway charged with homicidal offences, and in thirty-six cases the victims had been infants under 12 months old. Dr. Matheson divided these cases into two groups: one for the period from the beginning of 1936 until June, 1938 (when the Infanticide Act of that year came into operation, repealing and re-enacting with modifications the provisions of the previous Act of 1922), and the other for the period from that date until December, 1940. During the earlier period seven of the women were charged at assizes with murder; during the second period, following the passage of the Act, no such cases occurred. The accused women were most commonly between the ages of 20 and 30, and there was no case over 40. Of those in the earlier period nine were married women, eight of whom had had children before, and eleven were unmarried, of whom only one had had a child before; of those in the later period six were married, four of whom had had children before, and ten were unmarried, one of whom had previously had a child. The age of the victims was in the majority of cases under one month. Eleven of the twenty mothers relating to the earlier period, and eight of the sixteen mothers relating to the later period, had made preparations for confinement: the others had made none. As for the mental condition of these thirty-six accused persons, ten had had a positive history of mental impairment, and twenty-six a negative. Dr. Matheson's conclusions were that the lactational period is more important from this point of view than the period of pregnancy and childbirth, and that very often an exhaustion psychosis becomes evident. Infanticide is relatively more common among the unmarried than among the married, and among primiparae than among multiparae. There appears to be no specially favoured method of killing the infant, any one of a large number of methods being employed, and a true amnesia is not common. He did not think that the Act of 1938 had brought about any increase in the crime of infanticide. [The Act of 1938 applies to the killing of "a child under the age of twelve months" instead of to a "newly born" child as in the Act of 1922: it also refers to the effect of lactation as well as of pregnancy and childbirth.]

The Services

CASUALTIES IN THE MEDICAL SERVICES

ROYAL NAVY

Surgeon Lieut.-Commander JOHN WIDDICOMBE OLIVER, R.N., lost his life at sea in March while serving in H.M.S. *Bonaventure*. He was 33 years of age and was the elder son of Mr. and Mrs. Oliver of Old Bosham. He was educated at Felsted School and won a scholarship to Guy's Hospital, qualifying M.R.C.S., L.R.C.P. in 1931. For a time he was resident medical officer at Ashford Hospital. He entered the Royal Navy as surgeon lieutenant in 1931, and was promoted to surgeon lieutenant-commander in 1937. He was just posted to the Royal Naval Hospital, Haslar, for six months, and then served two and a half years on the China station in H.M.S. *Falcon*, Yangtze Flotilla, and returned to England to the Royal Marine Infirmary, Chatham, until August, 1936, when he was appointed to the Royal Naval Hospital, Great Yarmouth. He joined H.M.S. *Bonaventure* in April, 1940. He had been a member of the British Medical Association for ten years. He leaves a widow.

ARMY AWARD

The Military Cross has been awarded to Captain Prithvi Raj Bali, Army in India Reserve of Officers (Medical), in recognition of gallant and distinguished services in the Middle East.

The October issue of the *Dental Record* contains an entertaining account of the notorious mountebank commonly known as Sequah, by the well-known dental antiquarian Mr. B. K. Townend, who has collected from various sources a considerable amount of information about this extraordinary man. The bulk of evidence, according to Mr. Townend, goes to show that Sequah was born in Cornwall about 1844 and that his real name was William Henry Hartley. After serving in the police force he emigrated to America, where he achieved considerable success with his remedies, though not so great as he subsequently did in this country. On his return to England he successively started three companies in the course of three years, and during the 'eighties and 'nineties acquired a considerable fortune. His activities were not limited to this country, but he visited Tangier and Egypt, where he carried on his performances under the name of Sikwa. Though best known for his extraction of teeth in the market place of towns and villages, which he carried out to the accompaniment of a band and dressed as an Indian chief, he also professed to cure chronic rheumatism, deafness, blindness, rickets, consumption, piles, and all incurable illness. He also probably acquired large profits from the sale of his medicines, the most famous of which were "Sequah Oil," "Prairie Flower," and "Swamp Root Medicine," as well as from a sale of booklets containing rhymes in advertisement of his medicines.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

In Congregation on April 26 a bequest was gratefully accepted from the executors of the late Charles Slater, M.A., M.B., formerly of St. John's College. This is a legacy of £4,000 to the University of Cambridge to be applied for purposes in any way connected with the teaching of or research work in medical science or any other science ancillary to medicine at the absolute discretion of the governing body for the time being of the University.

The following medical degrees have been conferred:

M.B., B.CHIR. (by proxy).—F. S. Jackson, T. W. Rowntree.

UNIVERSITY OF LONDON

The membership of Brigadier P. H. Mitchiner, M.S., F.R.C.S., as representative of the Faculty of Medicine on Convocation, who was due to retire on May 13, 1941, has been continued until May 12, 1942.

The following candidates have been approved at the examination indicated:

POSTGRADUATE DIPLOMA IN PSYCHOLOGICAL MEDICINE.—Helen Baker (with Mental Diseases (Psychiatry)). *Part A:* J. W. Affleck, A. A. G. Clarke, Portia G. Holman, Barbara E. Woodhead.

UNIVERSITY OF ABERDEEN

At a graduation ceremony on April 3 the degree of M.D. was conferred on I. Sacks, and the Diploma in Public Health was awarded to R. F. Macdonald.

The following medals were also awarded: Fife-Jamieson Memorial Gold Medal in Anatomy: W. Burnett. Chanock Gold Medal in Anatomy: M. R. Milne. Lizars Gold Medal in Anatomy: G. E. Mavor.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

Election of Fellows

At a meeting of the Royal College of Physicians of London on April 23, with Sir Charles Wilson, President, in the chair, the following were elected Fellows of the College:

Stanley Wyard, M.D.Lond. (London); John Inkster, M.D.Aberd. (Middlesbrough); James Browning Alexander, M.D.Glasg. (London); Hugh Spear Pemberton, M.B.Liverp. (Liverpool); Edwin George Bleakley Calvert, M.D.Belf. (London); Alexander William Hendry, M.D.Aberd. (Aberdeen); Montague Maizels, M.D.Lond. (Maidstone); Thomas Howard Crozier, M.D.Belf. (Belfast); Frank Alexander Knott, M.D.Lond. (London); Clifford James Fuller, M.D.Oxf. (Exeter); Cyril John Polson, M.D.Birm. (Leeds); Robert Klaber, M.D.Lond. (Bishops Stortford); John Gerald Edward Hayden, M.D.Melb., F.R.A.C.P. (Melbourne); Robert Merttins Bird Mackenna, M.D.Camb. (Liverpool); Charles Percy Pinckney, M.B.Camb. (London); Swithin Pinder Meadows, M.D.Lond. (London); Andrew John Morland, M.D.Lond. (London); Francis Findley Hellier, M.D.Lond. (Leeds); Louis Philippe Eugene Laurent, M.D.Lond. (Basingstoke); Thomas Tennent, M.D.Glasg. (Northampton); John Guyett Scadding, M.D.Lond. (London); Norman Swift Plummer, M.D.Lond (Steyning); Ronald Wilson Fairbrother, M.D.Manch. (Wilmslow); Evan Jones, M.D.Lond. (London); Eric Hamilton Hudson, M.B.Camb (London); Max Leonard Rosenheim, M.D.Camb. (London); Samuel Nevin, M.D.Belf. (London); Gordon Wilkinson Goodhart, M.D.Camb. (London); George Norman Myers, M.D.Durh. (Cambridge); Eric Frank Scowen, M.D.Lond. (London); Alfred Ernest Barclay, M.D.Oxf. (Oxford); James Frederick Brailsford, M.D.Birm. (Birmingham); Robert Montgomery Gordon M.D.Dubl. (Liverpool); and Noel Gordon Harris, M.D.Lond (London). George Cranston Anderson, M.D.Ed. (London); Gordon Roy Cameron, M.B.Melb., D.Sc. (London); Egbert Coleby Morland, M.D., F.R.C.S. (Aylesbury); and Major-General H. Marrian Joseph Perry, C.B., L.R.C.P. & S.I. (London), elected under By-law XXXIX (b).

Surgeon Vice-Admiral Sir Reginald Bond was re-elected representative of the College on the Professional Classes Aid Council. Dr. G. E. Ward was appointed External Examiner in Medicine for the Fellowship Examination of the Faculty of Radiologists.

Admission of Members

The following candidates having satisfied the Censors' Board were admitted Members:

Hector John Anderson, M.B.Camb., Desmond William Ronald Ashby, M.B.Lond., Colin Ross Baxter, M.B.St.And., Harold Williams Fullerton, M.D.Aberd., Lilias Margaret Patria Gairdner, M.B.Lond., Ian Mills Hall, M.B.Lond., Michael Redmond Hayes, L.R.C.P., Frederick Roland George Heaf, M.D.Camb., Cecil John Charles Guy Hodson, M.B.Lond., Arnold Langley Jackson, M.B. Camb., Bertram Alfred Edward Johns, M.B.Birm., Thomas Arthur Kemp, M.B.Camb., Anthony Arthur Gough Lewis, M.B.Lond., Ronald Charles Mackeith, M.D.Oxf., Maurice Nellen, M.B. Capetown, John Wylmer Paulley, Flying Officer, M.B.Lond., John Pemberton, M.D.Lond., John Lawrence Pinniger, M.B.Oxf., Mohammed Sadiq, M.B.Punjab, Dwijendra Bhuson Sen, M.B. Calcutta, John Rupert Squire, M.B.Camb., Euodia Davel Van Der Walt, M.B.Capetown, Alfred John Walker, M.B.Lond.

Licences and Diplomas

Licences to practise physic were conferred upon the following 171 candidates (including 14 women) who had passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Board and have complied with the necessary by-laws:

P. H. Abbott, G. C. Acres, R. A. Allen, M. W. Annear, Norah H. L. Armstrong, F. Barasi, R. F. G. Barker, J. S. Barr, J. Ll. Battle, J. W. R. Battram, C. L. F. Beaton, R. C. Bell, W. Black, P. H. Blackiston, D. V. V. Bowen-Jones, K. G. Bowker, A. C. Boyle, W. Ll. Brace, K. T. Brown, J. E. Bulow, H. C. Burbridge, H. C. Burnell, I. C. Campbell, L. S. Carstairs, Joan Cleland, Betty J. Clymo, R. C. Connolly, P. B. Conroy, H. Conte-Mendoza, C. F. Cooper, W. H. Craike, R. McK. Crichton, J. H. Crosland, P. S. Cuthbertson, R. Daley, P. G. Dalgleish, G. J. Ll. Davies, H. Mel. Davies, B. W. Davy, T. Dean, R. M. de Gregory, W. P. Dick, R. G. Dickinson, C. F. Donovan, B. B. Downman, C. H. Dunn, J. R. G. Edwards, Margaret Edwards, J. J. Elkeles, B. Ellenbogen, F. Fessler, E. Finsterbusch, Elizabeth H. Flett, L. P. R. Fourman, H. D. Freeth, B. Galandauer, R. M. Galvan, L. A. Gibbons, N. W. Gill, Kathleen M. Gillett, N. Glas, N. F. C. Gowing, E. A. Grau, C. Greenwood-Penny, K. E. A. U. Ground, T. E. Hall, R. C. Hallam, G. J. Hardaker, D. H. C. Harland, S. Harrison, H. G. Helm, G. W. D. Henderson, R. S. Henderson, P. R. Henson, E. Hesselberg, R. D. Hoare, A. Holmes-Smith, H. Howard-Swaffield, H. B. Hyman, J. B. Ingram, C. J. R. Jacob, H. M. Jones, H. H. Khan, R. A. B. Kinloch, H. G. S. Kerwin, W. S. S. Ladell, S. E. Large, J. B. Latto, R. R. Latto, T. E. Lamb, B. Lees, E. J. Leighton, H. M. Lewis, D. M. N. Longridge, T. H. McCall, J. G. McGavin, Lydia McMurdo, F. R. L. Makin, C. N. S. Manson, J. K. Martin, L. G. C. Martin, Margaret E. Matthews, J. Le F. Milburn, P. J. Miller, R. A. Moir, B. P. Moore, D. B. Morgan, A. B. Morrison, A. R. V. Moynagh, A. B. S. Mules, A. T. L. Norfolk, N. C. Norman, J. A. Oddie, Thora A. M. Oehlers, K. R. Ogilvie, L. J. Page, K. H. J. B. Parker, T. P. Pattinson, R. H. Percival, C. M. C. Potter, Dorothy P. Potter, B. S. Powell, G. C. Price, G. C. Purslow, P. A. B. Raffle, R. I. Randall, D. Ranger, J. Reiss, L. Rendell-Baker, J. L. Roberts, T. M. C. Roberts, P. J. Robinson, W. J. B. Rogers, M. S. Ross, B. Rowlatt, F. R. Russell, H. B. L. Russell, J. A. Sadler, R. G. Saipe, R. P. G. Sandon, R. D. W. Schofield, R. Sepson, P. C. Sharma, R. M. Sharpe, K. N. Sinha, P. A. J. Smith, R. A. G. Smith, T. H. S. Smith, C. C. Spicer, W. Spitzer, J. S. Stead, D. E. S. Steele, H. Sterndale, S. J. Sutton, J. H. Thompson, Edith M. Thorp, J. S. Tomkinson, S. E. Vincent, J. W. Warburton, R. S. Wathes, N. D. Wayne, Christine M. Weddell, D. N. White, Mary White, G. L. Whitmore, D. M. Wilkins, Betty M. Williams, J. Williams, M. H. Wostenholm, G. B. Wright, R. B. Wright.

Diplomas in Child Health were granted, jointly with the Royal College of Surgeons of England, to the nine candidates whose names were printed in the report of the meeting of the Royal College of Surgeons of England in the *Journal* of April 26 (p. 656).

D. W. Martin (*J. Pediat.*, 1940, **16**, 468) states that since 1935 eight cases of Rocky Mountain spotted fever in children have been treated at the Duke Hospital, Durham, N.C., as compared with only three cases in adults. Two were taken ill in June, four in July, and two in August—that is, during the season of greatest activity of the dog tick, by which the disease is transmitted. In five of the eight patients a history of tick bites was obtained, with the onset of symptoms from three to fourteen days later. The character of the disease varied from no symptoms except a rash and a temperature of 104° F. to delirium, coma, and a temperature of 105° F. The average duration of fever was fourteen days. Only one patient had a complication—gangrene of the nose. All recovered. The disease cannot be diagnosed from typhus by the Weil-Felix reaction, but can be differentiated by inoculation of guinea-pigs and biopsy of the skin lesion. Treatment is purely symptomatic. Although there are no reliable figures on the mortality of the disease in children, the mortality rate appears to be much lower than in adults, while the morbidity is much higher. As regards prevention, control on a large scale is impossible owing to the rapid rate of multiplication of the ticks and their extraordinary resistance. The vaccine prepared by the United States Public Health Service usually protects for a year and reduces the mortality, but its cost makes its widespread use impracticable.

Medical Notes in Parliament

Distribution of Medical Man-power

Responding to a request by Sir Henry Morris-Jones, Mr BROWN on April 24 gave the recommendations of the Committee on the distribution of medical man-power between the several civil and fighting Services and general medical practice. These were:

(i) All medical establishments, Service or civil, should be reviewed forthwith with a view to the fullest possible utilization of medical personnel and the reduction of future demands.

(ii) The services of civilian practitioners in proximity to troops might be further extended.

(iii) Where the three Services in this country are represented in the same or adjacent areas, further economy should be effected by the adoption of the principle of area service

(iv) The possibility of temporarily releasing practitioners from the Services for civilian work through the winter months when the demands of the civilian population are greatest should be carefully examined.

(v) The employment of alien practitioners admitted to the *Register* in civil hospitals and the Services should be further extended.

(vi) The employment of final-year students as house-surgeons or house-physicians in civil hospitals should be set on foot.

(vii) The question of the employment of more practitioners from the Dominion of Canada and other Dominions should be further explored.

(viii) The possibility of recruitment of practitioners from the United States of America is a new factor, and action in regard to it should be taken as quickly as possible.

(ix) An effective organization for the settlement of questions of priority should be established.

Medicine Stamp Duties Deputation

In the absence of Sir Francis Fremantle, Captain G. S. ELLISTON headed a deputation to Mr. Ernest Brown on April 22 on the Medicine Stamp Duties. Lord Horder, Lord Wolmer, Dr. Howitt, and Sir J. Graham Kerr were in this deputation. Its spokesmen pointed out that the removal of the duties would increase the advertisement, distribution, and display of proprietary remedies in small packets, encouraging self-medication in place of early treatment by medical practitioners or in the hospitals, sanatoria, and clinics provided by local authorities. Mr. BROWN promised careful consideration of the arguments of the deputation with a view to further discussion.

Disability and Deaths from Silicosis

On April 22 Mr. HERBERT MORRISON, replying to Mr. James Griffiths, issued the following table giving particulars of applications to the Silicosis Medical Board for certificates under the Various Industries (Silicosis) Schemes for Coalminers, 1940.

	Total	South Wales, excluding Anthracite Mines	Anthracite Mines
Disablement or Suspension:			
Number of applications for certificates..	957	353	472
Number of certificates granted:			
(i) Total disablement	185	91	71
(ii) Suspension (with partial incapacity)	282	78	189
Deaths:			
Number of applications for certificates..	137	84	32
Number certified as due to the disease ..	93	58	18

Shortage of Hospital Lay Staffs

Lord GREVILLE, in the House of Lords on April 23, asked what the Minister of Health was doing to see that the civilian staff of hospitals was made a reserved occupation. Staff, especially female staff, was being lost at such a rate that some wards in hospitals might have to be closed. The only people reserved apart from nurses and doctors were porters over 30, pharmacists at 25, and the assistant secretary at 30. The Minister of Health should approach the Minister of Labour. Among the many men and women now registering there should be categories unsuitable for munitions work, fire-fighting, and A.R.P., but willing to work in hospitals. If the Ministry of Health would draw attention to these vacancies in hospitals the services could probably be kept going.

Lord CROFT, in reply, said the Minister of Health had in mind the difficulties of hospitals in maintaining adequate male staffs. He kept in touch with the British Hospitals Association and the Ministry of Labour on the problem, but was bound to recognize that voluntary hospitals, equally with local authorities, must make their contribution of men to the Forces, and that both must employ women substitutes wherever possible. The Schedule of Reserved Occupations published just before Easter should allow ample time to train women substitutes or older men. By this Schedule hospital secretaries were reserved at 25 until Stage B was reached, when the reservation age was raised to 30, rising at Stage C to 35. For other administrative and clerical staff the age remained at 30 until Stage C, when it rose to 35. Individual cases of difficulty could still be considered on their merits. Similar consideration had been given to the subordinate grades. Hospital porters remained reserved at 30. Hospital orderlies were still reserved at the same age, and could only be recruited below it if required for similar work in the Forces. Lord Croft referred to the appeal made by Mr Brown on April 3 for women to come forward for nursing duties. The registration of young women with the Ministry of Labour would also be used so far as possible for meeting the needs of those hospitals that were particularly short of domestic staff. Arrangements had been made for the hospitals to notify their needs locally to employment exchange managers. Women already employed in hospitals would be encouraged to stay there.

E.M.S.: Private Houses as Hospitals

Mr. K. LINDSEY asked on April 24 how many private houses had been set aside for hospitals. Mr. BROWN replied that under arrangements agreed with the War Organization of the British Red Cross Society and the Order of St. John of Jerusalem, 163 houses had been opened with 8,454 beds, and fifty-two more were in preparation with 2,531 beds as auxiliary or convalescent hospitals for the Emergency Hospital Scheme. In these houses 2,795 beds were at present occupied. Instructions to bring more beds into use were being issued. The usefulness of these hospitals did not depend only on the present occupancy of beds. They were required for relieving the main hospitals of suitable types of patients as and when the pressure on beds developed. Twelve houses had also been opened with 683 beds, and forty-four were in preparation with 2,459 beds, as annexes to existing hospitals. The occupancy of beds in these was pooled with the parent hospitals, and separate figures could not be given. In addition 9 houses, capable of providing 850 beds, were included in the buildings marked as reserved hospitals for use only in a serious emergency. All these figures related only to the Emergency Hospital Scheme in England and Wales, and did not cover other hospitals not in the scheme which made arrangements of this kind privately or premises used as sick bays or minor infectious diseases hospitals. Certain other buildings besides private houses were used or have been marked for hospital purposes.

Employment of Alien Doctors

In a reply on April 24, Mr. JOHNSTON, Secretary for Scotland, said Circular No. 2315 authorized the employment of doctors of enemy alien nationality at hospitals and similar institutions where members of the Forces received treatment. Mr. Herbert Morrison concurred in the terms of that circular, and, together with the competent military authority where necessary, was consulted on each individual case. Mr. Brown had adopted the same policy and procedure. In view of the heavy demands now made on British practitioners, Mr. Johnston was satisfied that no restriction was required which would prevent alien doctors practising in protected areas or other places where members of the Forces received treatment.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

The incidence of whooping-cough in England and Wales, generally throughout the country, showed a rise for the third consecutive week. This was mainly due to an increase in the prevalence of the disease in the urban areas. In Scotland the notifications showed a substantial decrease on the number for the preceding week. Fewer cases of diphtheria and scarlet fever were reported than in the preceding week, and in no area was there any violent fluctuation from the number of the previous week. The number of cases of cerebrospinal fever has been practically constant in England and Wales during the past four weeks, and no area has shown any considerable weekly variation. Two cases of typhus were recorded in Eire, from the rural district of Mohill, Co. Leitrim. The paratyphoid epidemic in the Highlands of Scotland is subsiding; the number of fresh cases reported during the week, 40, was less than half of the number notified during the preceding week.

Measles

The incidence of measles has risen considerably during the week under review, but the number of cases is below that recorded during some of the earlier weeks of the year. Compared with the previous week, increased notifications were recorded from Buckinghamshire, Essex, Gloucestershire, Lancashire, Lincolnshire, London, Suffolk, Surrey, Warwickshire, and Wiltshire. In the rural districts of Buckinghamshire the cases rose from 101 to 190; in Lincolnshire, Boston R.D., from 28 to 144; in Suffolk, Haverhill U.D., from 4 to 68; in Warwick, Birmingham C.B., from 396 to 593; in Wiltshire, Chippenham M.B., from 34 to 100. Contrary to the general experience of the country, the number of cases declined considerably in Dorset, from 349 to 182, and in Glamorganshire from 729 to 591—resulting from a fall in the incidence in urban areas. The increase in Scotland was due to the experience of Edinburgh and Glasgow, where 18 and 23 cases in excess of the preceding week were returned; but in Greenock a decrease of 26 occurred.

Dysentery

Although the total number of cases of dysentery was greater by 33 than that recorded in the preceding week, the general tendency was to a decline in incidence. The downward trend was disturbed by a violent outbreak in Hemel Hempstead, Herts, where 79 cases were reported for the first appearance of the disease in that area. This number was almost half the total recorded for the country. An investigation into the cause of this outbreak is proceeding, and all farms and dairies have been visited, as contaminated milk is suspected.

Trichiniasis

Rats have been found infected with the *Trichinella spiralis* in South Staffordshire, and the possibility of infection being spread by rats is being examined. Early in the year some 500 people were affected by this disease in Wolverhampton through, it is believed, eating raw sausage; but the actual source of infection was not established. There have been no fresh cases in the town during the past two months.

Typhus in Spain

Reports have been received that typhus fever is rife in several districts in Spain. The latest district to be affected is Algeciras.

Notifications of Infectious Diseases in England and Wales during the 26 weeks October–March, 1936-41

	1940–1	1939–40	1938–9	1937–8	1936–7
Cerebrospinal fever	6,138	5,432	734	721	588

A leading article on the incidence of epidemic diseases during the past winter appears at page 673.

No. 14

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended April 5, 1941.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1941 (a)	(b)	(c)	(d)	(e)	1940 (Corresponding Week) (a)	(b)	(c)	(d)	(e)
Cerebrospinal fever	335	19	81	3	7	436	38	86	4	5

Medical News

The address of the Chief Inspector of Factories is now Queen Anne's Chambers, 28, Broadway, S.W.1.

At the annual meetings of the Golden Square and Central London Throat, Nose, and Ear Hospitals, held on April 23, Lord Erskine of Restormel stated from the chair that arrangements were well in hand for completing the legal formalities of the amalgamation of the two hospitals. The committee had been greatly encouraged by the King's permission for the combined institution to be called the Royal National Throat, Nose, and Ear Hospital.

In place of the annual dinner the Society of Radiographers held a luncheon on April 26, when a company of nearly one hundred assembled under the chairmanship of Mr. C. W. Furby. The proceedings were overshadowed by the recent death of Dr. G. W. C. Kaye, who had been president of the Society since 1937; and many tributes were paid to him at the gathering. In proposing the health of the Society, Lieut.-Colonel D. B. McGrigor, President of the British Institute of Radiology, congratulated radiographers on the work they were now doing in many spheres, civil and military, at home and abroad. Mr. Furby, the acting president, responding, said that the Society was now between 1,300 and 1,400 strong. He thanked Mr. F. Melville for his devoted work as secretary. Mr. Cuthbert Andrews, in proposing the health of "The Guests," said that they included representatives from the branches and allied societies and members of the *x*-ray services of the United States and Canada who were in this country. Major Boulton Myles, honorary secretary of the British Institute, said that he was in command of the R.A.M.C. School of Radiography, which was seeking to instil into the people concerned sufficient knowledge to enable them to make intelligent use of the *x*-ray apparatus being issued to the Army Medical Service, and he counted himself fortunate in being able to enlist the Society's co-operation in this respect.

On April 23 the American Ambassador handed to the chairman of the Women's Voluntary Services for Civil Defence three cheques totalling £70,250 as a gift from the American Red Cross Committee in Great Britain. Of this sum £20,000 will be used to establish thirty more nurseries for children under 5 years of age, including £5,000 to establish convalescent homes for bombed children who are not fit to go directly to the nurseries. The nurseries were started by the Women's Voluntary Services at the request of the Ministry of Health. There are already forty-six war nurseries, maintained by a grant of £20,000 from the American Red Cross. Every effort is made to send only normal healthy children to the nurseries. A further £50,000 is to be used in establishing seventy nursery centres at a cost of £700 each and £250 for play and instructional equipment for the existing nurseries. These nursery centres provide skilled attention for small groups of evacuated children during the daytime, giving them social training and occupation, a midday meal, medical supervision, and healthy surroundings.

Lord Horder has been elected president of the Cremation Society in succession to the late Duke of Bedford. He will continue to act as chairman of the council. Last year the number of cremations was 25,175.

Dr. Kenneth William Cripps Sinclair-Loutit, medical officer, A.R.P. Casualty Service, Finsbury, has been appointed an M.B.E. (Civil Division) for brave conduct in civil defence, and the names of Dr. John Balfour Allan and Dr. Herbert Beaton Giles, Casualty Service, Lincs (Kesteven), and Dr. James Macpherson, medical practitioner, Westminster, have been brought to notice for brave conduct in civil defence.

Dr. Alfred William Lumsden Smith has been nominated as a candidate for the Parliamentary constituency of King's Norton, Birmingham, rendered vacant by the death in action of Major J. R. H. Cartland. Dr. Lumsden Smith describes himself as an "independent reprisal candidate."

At the annual general meeting of the Royal Sanitary Institute the Earl of Bessborough was elected President in succession to Lord Balfour of Burleigh, whose period of office had expired.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE NO.—B.M.A. and *B.M.J.*: EUSTON 2111.

TELEGRAPHIC ADDRESSES: EDITOR, *Aitiology Westcent, London*; SECRETARY, *Medisecra Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

QUERIES AND ANSWERS

Defect of Micturition

"EXILE" writes: The contrivance suggested by Dr. W. M. M. Jackson (September 7, 1940, p. 344) in response to the query of "Puzzled" (August 31, p. 306) may be avoidable. I am but 27 and have had this difficulty for as long as I can remember (diagnosis ?). Pressure over the bulb of the urethra, an unobtrusive manœuvre, should express these last few drops.

Income Tax

Use of House in Absence on Service

"J. H." is a partner in a firm of two; he is a bachelor, and a locumtenent is living in his house and carrying on his work. Can he deduct the whole of the cost of upkeep of the house or only the former one-third?

∴ The house presumably serves the purposes of storing his furniture, etc., and providing a place of residence for him as and when he can use it or return to it. A claim to deduct the whole is therefore not a valid one. On the other hand, that part which is being used for the personal accommodation of his employee (the locumtenent) is now being used for the purposes of the practice, and a larger proportion than formerly is due. We suggest that a claim for two-thirds would probably be a reasonable compromise.

Payment to Wife for Assistance

"COUNTRY DOCTOR" has paid his wife £52 a year for over twenty years, "as she acts as my secretary, does my books and accounts, and is a trained nurse and attends to accidents and dressings." No allowance for this was claimed until this year. Can he now claim for past years?

∴ Yes; a claim can now be made under the "error or mistake" provision (Finance Act, 1923, Section 24) for repayment of the excess tax paid for the five financial years 1934–5 to 1939–40. It will, however, be necessary to show that the £52 a year was paid to the wife *as remuneration for services*. In a case heard in the High Court in 1927 (Thompson v. Bruce) a refusal to admit a claim was upheld on the ground that there was no satisfactory evidence of such payments having been made.

LETTERS, NOTES, ETC.

Convulsions under Anaesthesia

DR. W. MATHEWS (Barrow-in-Furness) writes: The following account of a case of so-called ether convulsions may be of interest. Male, aged 31 years, suffering from perforated gangrenous appendicitis, which began sixty hours before operation. Before operation the temperature (mouth) was 100° F., general condition apart from the abdominal trouble was good; he had morphine, 1/4 grain, and atropine, 1/100 grain, thirty minutes before operation. The anaesthetic was chloroform and ether in the proportion of 1:3 (open mask), changed to pure chloroform fifteen minutes after the operation began. Half an hour after the start of the anaesthetic convulsions began, first in the face and extending in a few minutes to the whole body. The patient became very cyanosed, and oxygen in a high concentration was given for about five minutes, with relief of cyanosis, but convulsions were becoming more violent. Sodium evipan, 5 c.cm., was then given intravenously in about one minute with immediate cessation of the convulsions. The patient was returned to the ward, and recovery from the anaesthetic was normal. The temperature thirty minutes after operation was 102.4° (axilla).

The temperature of the theatre was 80° F. The anaesthetic was not an orthodox one, but I think it suggests that ether is not the cause of these convulsions.

Rotary Pump in Intravenous Therapy

Dr. R. N. HERSON (Middlesbrough) writes: All the advantages claimed by Mr. G. M. Arnott for Riddell's rotary pump (April 5, p. 517) can be equally well secured by a much cheaper and simpler device. If to his short bent tube which passes through the rubber bung of a wide-necked bottle a pair of bellows is attached, the siphonage can easily be started (provided that his straight inlet tube is dispensed with). The bottle is then raised a few feet above the vein. The bellows can be removed once the siphonage is established. As occasion arises the bellows are reapplied and a little more air is forced into the bottle to speed up a sluggish drip. A suitable pair of bellows will be found in most hospitals as part of the sigmoidoscopic equipment. For the rest, all that is required are a bottle, pieces of glass tubing, rubber tubing, a drip chamber, and a cork. Incidentally, this method has the advantage over Riddell's pump in that the same pair of bellows can be used to start and maintain several transfusions at the same time.

Local Treatment with Sulphonamides

We have received from Pharmaceutical Specialities (May and Baker) Ltd. a pamphlet entitled "The Prevention and Treatment of Infection in Wounds by Sulphonamides," which reviews present knowledge of the effects of introducing sulphonamide compounds directly into wounds: twenty-eight references are given to original papers. It is concluded that this practice has some preventive but no curative value, that it should be reinforced by oral administration, and that in wounds involving nervous tissue it should be avoided. A copy of this publication will be sent by Messrs. May and Baker to any medical practitioner on request.

The Future of Dentistry

Mr. J. E. BOOKER writes on behalf of the Joint Planning Committee of Dental Students (c/o National Dental Hospital, Great Portland Street, W.1): There has been a good deal of discussion recently within the medical profession with regard to the post-war adaptation of medical services to meet the best interests of the community under the new conditions which must inevitably arise. This problem has seriously presented itself to the students of the dental profession, and a Joint Students Committee, representative of all the London dental hospitals, and later, we hope, to include representatives of all the provincial hospitals, was formed some weeks ago and held its first meeting on March 13. The primary object of the committee's efforts is to further in post-war Britain the best ideals of public service, and with this end in view to equip the future dental practitioner with a detailed knowledge of both the good, and in particular the bad, conditions existing in modern dentistry. Already a comprehensive schedule, consisting of one hundred and ten items under five subdivisions, has been prepared, and this, we believe, covers all the major and associated problems confronting the dental profession. Dentistry, in common with medicine, is a vital public health service, and as such we feel that no effort should be spared in mobilizing the great scientific developments which have taken place since the early days of the profession in order that they may be made available to every class of the community. We feel that, for the complete accomplishment of our ideals, absolute co-operation is necessary between the dental and medical professions. Our own programme involves a great deal of self-criticism, and we would welcome any suggestions in the nature of co-operation which the medical profession may wish to make. For our part we shall be pleased to keep in touch with any similar movement to our own which may exist now or in the future within the medical profession with a view to free interchange of ideas and suggestions. Such co-operation between students of the two professions would do much to create a complete and mutual understanding of the paths along which each profession must tread in common and those from which a divergence is necessary by the special nature of the work involved. We would like to see such divergent paths eventually running parallel, with wide channels of communication through which could pass swiftly details of modern research and technique. The British Dental Association has been approached, and has expressed its approval of the proposed activities of the Students Joint Planning Committee.

Elastic Stockings

Dr. W. M. M. JACKSON writes: Elastic stockings should be made to measure and not purchased ready-made. Makers who advertise in the *Journal* have experienced fitters and can be relied upon for fit and quality. It is not necessary to purchase the more expensive qualities. Care should be taken to assure that the stocking is quite loose at its upper free border. It should be put on in the morning before rising. This is best done with the leg and thigh elevated at right-angles to the recumbent trunk; this position ensures emptied veins. In order to extend the durability and elasticity of the stockings, duplicates should always be ordered. By wearing on alternate days they have a rest of a day or more to dry and retain their shape. They last longer kept unexposed to light. I have found it comfortable and convenient to change them before dinner in the evening. They are, of course, removed when the wearer is in bed.

National Union of Students

Mr. P. A. H. RIVETT writes from the Leeds School of Medicine: I should like to correct any erroneous impressions which may have been created by the note in the *Journal* of April 12 (p. 578) referring to the decision of the Middlesex Hospital Common Room Society to withdraw from the National Union of Students on the grounds that the activities of the medical subcommittee of the union "no longer retained their non-political character." It has been a source of regret to the National Union that the Middlesex Hospital has never been a member, and has thereby been unable to voice its opinion at or to participate in the discussions and decisions of council, the governing body of the union. It has long been felt that this situation is to the disadvantage of both parties, in that the union is deprived of the contributions of Middlesex and the hospital is unable to share in the control and privileges of the union. As the hospital has never been a member, however, the decision to withdraw means less than nothing. With regard to the so-called "political activities" of the medical subcommittee, since the society does not even trouble to send observers to its meetings it is somewhat difficult to understand upon what grounds this extraordinary view is based; I am convinced that it is an ill-informed and hasty judgment, and I challenge the secretary or any other member of the society to advance any evidence to substantiate the opinion of the society.

*** This question cannot be discussed further in the *British Medical Journal*.

A Monthly Gift to the Medical War Relief Fund

"NORTH WALES" writes: I have already made one small contribution to this Fund, but a few days ago I thought of a plan which may prove useful to others of my colleagues. I propose to call on my bankers this week and ask them to make a monthly payment of one half-guinea towards the fund, so long as I can do so. I shall not miss it by giving it in this fashion and, being a lucky one in an evacuated area, consider I should do more; by a monthly subscription I am more likely to give a larger sum in the long run. I hope this method does not involve too much clerical work for the good fellows concerned.

Ration Meals

Ration Dinners, a booklet on the lines of the B.M.A.'s *Doctor's Cookery Book* but adapted to war needs, has just been published by the Central Council for Health Education. It has been approved by the Ministry of Food; the instructions are simple and the methods advised are up to date. Under each recipe quantities are given for a family of four and for a canteen of 100 people. The booklet is attractively printed and illustrated, and may be obtained in bulk from the council's offices, Tavistock House, Tavistock Square, W.C.1, or from booksellers at 2d. a copy.

A Children's Rest Centre

Miss ANNA FREUD writes: In your issue of March 29 (bottom of p. 491) you mentioned that I have "opened a clinic in Hampstead . . . etc." This statement seems to be based on a misunderstanding. The house in question is no *clinic* but a Children's Rest Centre—that is, a place where bombed-out babies and children can find a home under favourable conditions. I should be grateful if you could publish this explanation.

Injuries from Lightning

Dr. F. R. HUMPHREYS writes from Langley Terrace, Oakes, Huddersfield: I should be grateful to any of your readers who would be kind enough to send me details of any cases of injury to human beings from lightning. War conditions make it difficult to get information. The information will only be used for statistical purposes in connexion with the Thunderstorm Census Organization.

Corrigendum

Dr. JAMES REID wishes to point out that in his article "Prothrombin Deficiency in Disease of the Liver" (*Journal*, April 19, p. 579) the method of calculating the prothrombin index was incorrectly stated. It should have read:

$$\text{Prothrombin index} = \frac{\text{Control prothrombin time}}{\text{Unknown prothrombin time}} \times 100,$$

this being the reverse of the formula as given by him.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY MAY 3 1941

British Medical Association

PROCEEDINGS OF COUNCIL

Wednesday, April 23, 1941

A meeting of the Council of the Association was held at B.M.A. House, Tavistock Square, London, on April 23. Mr. H. S. SOUTTAR, Chairman of Council, presided, and about thirty members were present.

Personal and Preliminary

The Chairman mentioned with great regret the deaths of three former members of Council—Drs. H. S. Beadles, E. W. Lewis, and E. O. Turner. He also drew attention to the honours recently conferred by the King upon a number of members of the Association.

It was announced that owing to the pressure of other duties Dr. W. G. Willoughby had resigned from the Council. His resignation was received with great regret, and the Council gave instructions that a special letter of thanks should be sent to him for his services in many capacities.

The Chairman, with whom Dr. Dain and Dr. Bone were associated, gave notice that at the next meeting he would move that the Gold Medal of the Association be conferred upon Sir Kaye Le Fleming in recognition of his distinguished work for the Association and the profession.

Milk Restrictions

A communication from the Ministry of Food was before the Council stating that in view of the restriction of the supply of milk to domestic consumers the Ministry was anxious to ensure that milk supplies were available for sick persons in private households. To this end the Special Diets Committee of the Medical Research Council, which had been consulted, had advised that special provision should be made for the following diseases or conditions: active tuberculosis of all types and of all organized tissues; silicosis; conditions in which the patient is unable to swallow solid food by reason of an affection of the mouth, throat, or gullet; gastric, duodenal, or anastomotic ulcer; illnesses characterized by high and prolonged fever; and post-operative conditions after major operations. It was also stated that the statutory order which promulgated the restriction scheme would provide a prescribed form of medical certificate, the production of which by the householder would authorize the dairyman to supply the sick person with the quantity of milk recommended by the doctor, and that the doctor should obtain from the local Food Office copies of the form.

Several members of the Council expressed the view that the list of conditions for which special provision was made, while well enough so far as it went, was rather restricted. Reference was made in particular to the difficulty of old people in getting the necessary supply. It was suggested that a further category should be made consisting of exceptional cases in which, in the opinion of the doctor, an extra supply was desirable. It was also considered to place an unnecessary burden on the practitioner that he himself according to the terms of the order should be required to go to the Food Office for copies of the certificate. It was agreed that the Ministry of Food be made acquainted with the views of the Council on these and other points.

The Central Medical War Committee

Mr. Souttar, in presenting the report of the Central Medical War Committee, said that certain special committees had been appointed—namely, a Services Committee to deal with the recruitment of individual practitioners, under the chairmanship of Sir Alfred Webb-Johnson, together with a Young Practitioners Subcommittee to advise on the recruitment of young practitioners, under the chairmanship of Prof. Picken; an Advisory Emergency Hospital Medical Service Committee to consider questions relating to the E.M.S., under the chairmanship of Sir Robert Hutchison; and a Grading Committee, to determine the grading of practitioners to be recommended for employment as consultants and specialists in the Forces, under the chairmanship of Dr. J. C. Matthews.

The Association's Prizes, Scholarships, and Grants

Mr. Souttar said that the Executive Committee had considered the policy to be adopted in regard to the award of the Association's prizes, scholarships, and grants during the period of the present emergency. It recommended that the prizes and grants be not awarded during that period. The recommendation was agreed to.

It was announced that the Sir Charles Hastings Clinical Prize for 1941, which was offered before the above decision was considered, had been awarded to Dr. Eustace Pell Edmends of Aylesford, Kent, for an essay on "A Year's Survey of Psychoneuroses in General Practice." The thanks of the Council were accorded to the examiners (Colonel Gordon and Sir Humphry Rolleston).

Association Finance and the Journal

The Treasurer (Dr. Bone) presented the Balance Sheet and Financial Statement appended to the Annual Report of Council. He said that one of the outstanding facts in the statement of accounts was that the *Journal* had been produced at a much lower cost than in the previous year. The result reflected great credit on the Board of Directors and on the editorial and administrative staffs.

Colonel R. G. Gordon, chairman of the Board of Directors, said he was sure the Council would like to thank the staff of the *Journal* for the extremely good work they had done under very difficult circumstances and also to welcome back the Editor. During his long absence at the close of last year Dr. Clegg, Deputy Editor, and Miss Hollowell, Subeditor, had done excellent work and had maintained the *Journal* at a very high standard. The Advertisement Manager also deserved congratulation on the fact that the revenue from advertisements had increased although the number of pages had been cut down very considerably. The printers deserved commendation for having carried on in the face of great difficulties. Colonel Gordon added that although the paper situation was difficult there was every hope of keeping the *Journal* at or about its present size, and every effort would be made to maintain its interest and topicality. The special journals had also come out very satisfactorily in the accounts.

The Medical Planning Commission and General Practitioners

Dr. E. A. Gregg reported that the Insurance Acts Committee had had under consideration representations made by a large number of panel committees for an increase in the proportion of general practitioners represented on the Medical Planning Commission. It had been decided to ask the Commission to agree to an increase in the number of urban and rural general practitioners on that body. It was also reported

that resolutions had been received from a number of panel committees and Divisions urging more direct representation of general practitioners.

Dr. Wand said that the amount of feeling on this subject in the country was very great, and he was sure that if the Council could see its way to endorse the action of the Insurance Acts Committee it would do a great deal of good. General practitioners were sore because, while the Royal Colleges had a direct representation of consultants, the general practitioners, though some of their number were on the Commission, had no such direct representation.

The Chairman of Council said that he would be glad to see the Insurance Acts Committee's proposal placed before the Commission. Dr. Waterfield said that the Council hardly realized the amount of feeling on this subject in the country. Various matters such as the failure to secure a higher capitation fee for insurance practitioners and the refusal of the Ministry to take into account increasing costs all reacted on the feeling of general practitioners. In the past members had had the opportunity at the Annual Representative Meeting and the Panel Conference of expressing their views, but this was denied them at present, and therefore they were passing resolutions at panel committee meetings and writing letters to the *Journal*.

Mr. Bishop Harman said that it was not desirable to enlarge the Commission, but he thought the Insurance Acts Committee might itself be regarded as a committee of the Commission within its particular province. Dr. Dain thought that the Council could hardly go back on the arrangements already made. The Association had with some difficulty secured a lead in this matter, and it was desirable that nothing should be done to imperil it. Colonel Proctor associated himself with what Dr. Wand had said, not only because the Division of which he was chairman had asked him to emphasize their point of view, but because at a meeting of the whole profession in his area, which was called to elect the Local Medical War Committee, the opportunity was taken of ventilating this grievance.

The Secretary, who addressed the Council by invitation, said that in view of the decision already taken with regard to the size of the Commission it would be very unwise to go back upon it, but it could be safely left to the chairman of the Insurance Acts Committee, who was himself a member, and to Dr. Dain and others to put forward to the Commission at its first meeting next month the point of view which had been expressed in the Council.

The Council adopted the report of the Insurance Acts Committee embodying the statement that the committee had decided to ask the Commission to agree to an increase in the number of general practitioners, and it was left to those members of the Council who were on the Commission and to the Officers of the Association to see what could be done when the meeting was held.

Mr. Souttar, speaking for the Executive Committee, said that consideration had been given to the question of holding a Representative Meeting during the present year, but it was decided that such a course was neither advisable nor desirable at the present juncture.

Prof. Picken said that while he agreed that an Annual Representative Meeting in the ordinary sense should not be held, it was very important that at a time when there was a certain amount of unrest among the general body of members a middle course should be taken. There was a good deal to be said for holding at the time of the statutory Annual General Meeting in July a special meeting or conference of representatives of Home Divisions at which there might be submitted the Annual Report of Council and any such agenda as the office might consider desirable. He hoped also that the publication of the Annual Report of Council would not be much curtailed. It was essential to convey to the Divisions and the general body of members throughout the country all that Council and headquarters were doing at the present time.

Dr. Peter Macdonald associated himself with the suggestion for holding a conference, and the Chairman of Council said that in fact this matter was at present under consideration by the Executive Committee and he hoped that it would be possible to carry it into effect.

Increase in Private Fees Recommended

Dr. Bone, reporting in the absence of Dr. Pooler for the General Practice Executive Committee, said that a few Divisions had recommended their members to increase their private fees in view of the rising costs incurred in medical practice, and the committee had considered whether the time had arrived for making a central recommendation on those lines. He moved accordingly:

> That an increase of fees has been rendered inevitable by rising costs, and that practitioners in general practice be recommended to increase their private fees, including contract fees, by not less than 20%.

He said that this followed the precedent made during the last war. The recommendation was agreed to.

Dr. Bone mentioned that the committee had for some time been in communication with the Ministry of Pensions in an endeavour to persuade the Ministry to increase the fees payable to practitioners acting as medical officers on the Ministry's medical boards. The Ministry of Pensions could not agree to the increase requested by the Association, but it had given authority for a certain upward revision. The committee was now asking the Ministry to discuss the position with representatives from the Association.

In response to a request for advice the committee had recommended that a fee of 5s. be paid for the examination of bus conductresses; also that the same amount be paid to the certifying factory surgeon for certificates of medical unfitness in the case of workmen who had been ordered to remove to areas away from their homes to take up work of national importance.

Scotland and Ireland

Dr. J. B. Miller presented a report from the Scottish Committee. He said that most of the counties of Scotland and the larger burghs were working the Maternity Services (Scotland) Act, 1937. He also reported that consultations had taken place between representatives of the Royal Infirmary, Edinburgh, and of the Edinburgh and South-East Scotland Branch of the Association, together with the Scottish Secretary, regarding the use of out-patient departments in the hospital. As a result a lengthy minute of eight clauses had been adopted by the Board of Managers of the hospital setting out the function of the out-patient department, and it had been agreed that the City of Edinburgh Division should notify the position to the practitioners in the area.

Dr. Peter Macdonald congratulated the Scottish Committee on an excellent piece of work in getting this statement of the functions of out-patient departments agreed, and Dr. Bone added his congratulations, saying that this terse and definitive statement might well be commended to the Medical Planning Commission when it was considering this subject.

Dr. David Gray, president of the Northern Ireland Branch, was nominated to represent the Association on the tribunal set up by the Ministry for Home Affairs in accordance with the first schedule of the Dangerous Drugs Regulations.

Other Business

A highly satisfactory report was received from the Medical Propaganda Committee. It was stated that the editors of forty British medical and related periodicals were assisting the British medical information service by sending their journals regularly for abstracts, and that batches of abstracts were being sent to periodicals in the Spanish language in Spain and in Central and South American countries.

The General Practice Executive Committee reported that the long night raids had caused some difficulty in assessing the fee to be paid to a practitioner called out for duty at a first-aid post for a period extending over midnight. The fee had been fixed at 1½ guineas for a session of not more than two hours and 3 guineas for a session of more than two hours, with a maximum of 3 guineas for any one day. The Ministry of Health's proposal to define "any one day" as the period from midnight to midnight had been accepted, anything less than one hour's attendance on either side of midnight not being reckoned as entitling the practitioner to a fresh day's sessional fee.

Routine reports were presented from the Industrial Health Committee and the Charities Committee, and the Annual Report of Council was approved for publication

The Certificates for Extra Milk

SIR,—I wish to protest against the new form of certificate for additional supplies of milk to persons suffering from certain diseases. What patient suffering from "active tuberculosis of the left lung" or "inability to swallow solid food by reason of a cancer of the oesophagus" wants to impart this information to his milkman? This factor will undoubtedly deter many patients for whom the scheme is intended from applying. By all means let the authorities instruct the medical practitioner as to what diseases "qualify ' for the extra milk—but as to broadcasting this confidential information to the dairyman—well!—I am, etc.,

Rayleigh, Essex, April 20. C. H. BATEMAN.

SIR,—There is a growing menace that has recently appeared in our midst ; I refer to the various types of certificate we are now called upon to complete to enable our patients to obtain meat instead of sugar, a different type of gas mask, or extra amounts of milk. In the latter case we are asked to complete a form specifying the exact nature of the disease from which the patient is suffering. This form, when duly completed by the householder, is then handed to the dairyman, who retains it until its period of validity has expired.

There appear to be several serious objections to this procedure. (1) We should not be asked to disclose the innermost secrets of our patients' bodies to the dairyman or any other interested or disinterested party. (2) In many instances it is most undesirable that the patient should have the opportunity of learning the exact nature of his disease—for example, "cancer of the oesophagus"—so glibly mentioned in the instructions. (3) The form when completed is only valid for one month except in exceptional circumstances, not specified, when most conditions for which the form will be used, such as pulmonary tuberculosis or gastric or duodenal ulceration, may require many months of, or even permanent, milk diet.

I consider this form implies a complete lack of confidence in the profession. Surely if we are considered an honest body of men all that should be necessary is for the profession to be circularized as follows: (1) Extra milk will only be supplied on written medical recommendation ; (2) only up to two pints daily can be granted ; (3) the period specified should not exceed three months ; (4) only for certain conditions, of which a list is given, will extra allowance be permitted; this would then enable us to deal very quickly with any patients who should approach us for extra milk with inadequate reasons.

Is it not cause for concern when a patient is faced with the alternative of publishing the fact that he is suffering from dysphagia due to an aneurysm of his aorta or starving to death? Is it not cause for concern that we are made to forfeit what has always been one of the finest traditions in our professional code? In conclusion, may I quote a passage from the Hippocratic Oath, which runs: "I will keep silence regarding that which, within or without my practice, I shall see or hear in the lives of men which should not be made public ; holding such things unfit to be spoken."—I am, etc.,

Southend-on-Sea, April 21. H. WALMESLEY GREENWOOD.

*** The Secretary of the B.M.A. states that this matter and others in connexion with the certificates for extra milk have been taken up with the Ministry of Food.

Discrepancies in Health Insurance Benefits

SIR,—Numerous letters have been published in the *Journal* recently on the future of medical practice, yet no one has mentioned the greatest scandal present in National Health Insurance practice to-day—a scandal which, if left unchecked, will be even greater with any extension of the N.H.I. system. I refer to the discrepancies between the benefits and sick pay distributed by the various Approved Societies. Surely it should be axiomatic that when all (of the same sex) pay the same premiums, all should receive the same benefits ; yet any practitioner who troubles to ask his patients will find that there is a difference—often of several shillings—between the cash benefits paid by different societies, while the differences between dental, ophthalmic, and "special appliance" benefits are even more marked and confusing.

Before the panel system is extended to higher income levels let the State take over the N.H.I. side of *all* the Approved Societies. Let every insured person be assured of a reasonable cash benefit when sick, together with full dental and ophthalmic benefits. Finally, let the economies so effected (by the State running one office and one agent for every dozen or more competing offices and agents to-day) provide an efficient pathological service for insured patients and a reasonable capitation fee for insurance practitioners. The advantages of such a scheme seem obvious. No additional money should have to be found by the State or the taxpayer, and a more efficient, better-paid service would be provided for patients and doctors alike. Why should any corporation or company profit by a State tax?—I am, etc.,

Prees, Shropshire, April 22 G. H. M. FRANKLIN.

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W.—*Daily*, 10 a.m. to 4 p.m., Medical Clinics, Surgical Clinics and Operations. Obstetrical and Gynaecological Clinics and Operations. *Daily*, 1.30 p.m., Post-mortem Demonstrations. *Tues.*, 11 a.m., Paediatric Clinic. *Wed.*, 11.30 a.m., Conference (Medical) ; 2 p.m., Blood Substitutes in Transfusion. *Thurs.*, 2 p.m., Dermatological Clinic ; 2 p.m., Radiological Demonstration. *Fri.*, 12 noon, Conference (Surgical) ; 2 p.m., Conference (Gynaecological) ; 3 p.m., Sterility Clinic.

DIARY OF SOCIETIES AND LECTURES

EDINBURGH POSTGRADUATE LECTURES.—At Edinburgh Royal Infirmary, *Thurs.*, 4.30 p.m. Dr. M'Whirter: Progress in Treatment of Malignant Disease.

DAVYHULME MILITARY HOSPITAL MEDICAL SOCIETY.—*Thurs.*, 5 p.m. Dr. P. B. Mumford: Common Infective Disturbances of the Skin.

HARVEIAN SOCIETY OF LONDON.—At 26, Portland Place, W., *Mon.*, 2.30 p.m. Dr. John Taylor: The Coroner, the Doctor, and the Public.

B.M.A. : Branch and Division Meetings to be Held

EAST YORKSHIRE BRANCH.—At City Restaurant, Lowgate, Hull, Wednesday, May 7, 8.45 p.m. Annual General Meeting. Presidential Address by Dr. I. G. Innes: A State Medical Service. Preceded by supper at 8 p.m.

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than the first post Tuesday morning to ensure insertion in the current issue.

BIRTH

SMITH.—At the Lucy Baldwin Maternity Hospital, Stourport, to Jane Ellen (*née* Jones), wife of J. A. Smith, M.R.C.S., L.R.C.P., Barnsley Hall, Bromsgrove, a daughter.

MARRIAGES

CYRLAS-WILLIAMS—COLYER.—On April 18, at St. Michael's Church, Maidstone, R. W. Cyrlas-Williams, M.A., M.R.C.S., L.R.C.P., to Ruth Colyer, M.R.C.S., L.R.C.P.

TEMPLE—LEIGHTON.—On April 21, at Norwich, John Lloyd Temple and Charlotte Mary Leighton.

DEATHS

DURNO.—On April 28, 1941, at 22, Gelliwastad Road, Pontypridd, Wales, John Durno, M.D., age 83 years, late 168, Coldharbour Lane, London, S.E.5.

MORGAN.—On Sunday, April 20, 1941, at 35, North Parade, Aberystwyth, Morgan John Morgan, M.D.Brux, M.R.C.S., L.R.C.P., D.P.H., aged 70.

WATSON.—On April 23, 1941, at "Ormanli," Sandown Drive, Sale, Cheshire, Charles Watson (retired), L.M.S.S.A., age 64 years.

PULMONARY TUBERCULOSIS IN RECRUITS

FURTHER EXPERIENCE IN A SURVEY BY THE METHOD OF MINIATURE RADIOGRAPHY

BY

DOUGLAS GALBRAITH, M.D., F.R.A.C.P.

Major, Deputy Assistant Director-General of Medical Services, Australian Army Medical Corps

To judge by the correspondence in the medical journals that has followed the paper on this subject by Lieut.-Colonel E. L. Cooper (1940) the use of the method of miniature radiography by the Australian Army for the routine chest examination of recruits has created wide interest. The number of examinations during 1940 was more than 100,000, and it seems worth while to place the results on record. The most important reason, however, for a progress report on the subject is that striking confirmation of the value of this work has been obtained by Dr. Reginald Webster, pathologist to the Melbourne Children's Hospital, whose detailed results are recorded on page 701. Dr. Webster has had outstanding experience in this field, and the results of his investigation represent a considerable contribution to tuberculosis research. While there must always be a scientific doubt in regard to the radiological diagnosis of tuberculosis, there can be little objection to a diagnosis established by sound bacteriological methods.

Cost of Method.—Careful figures of cost have been maintained throughout in all the military commands. The cost per recruit has consistently averaged between 5d. and 6d. This figure covers cost of all films, miniature and 14 by 17 inch, cost of processing, wages of staff, and salaries of specialists. A liberal allowance for maintenance and for depreciation of plant brings the total cost for each recruit to an average of 10d.

Survey of Results and Value of the Survey

From the various military commands in Australia the results of the examination of more than 100,000 Army recruits are available. All these recruits had passed the clinical medical examination. Of this number 1.04% showed radiological evidence of active or latent tuberculosis of the reinfection type, thus representing rather more than 1 in 100 of those examined. In 0.56%, or rather more than 1 in 200, the condition was regarded as being active. These figures approximate very closely those reported by Lieut.-Colonel E. L. Cooper for the first 22,000 recruits examined. For obvious reasons the exact number of recruit examinations cannot be given, but it can be stated that considerably more than 1,000 recruits showed radiological evidence of active or latent tuberculosis of the reinfection type. In addition approximately 1 in 400 showed non-tuberculous pulmonary conditions on the radiograph and 1 in 1,000 had cardiac or vascular abnormalities. The detailed results are given in Appendix I.

Disregarding the humanitarian aspect and examining the problem strictly from the Army standpoint, the most important factors which operate when a soldier develops active tuberculosis are: (1) the loss of his services and of the work hours spent in giving him his military training; (2) the danger of his infecting others in the close proximity entailed in hutments and tents; (3) the financial loss to the taxpayer represented by the cost of treatment and by pension. The first factor is self-evident and need not be stressed. The second is dealt with convincingly by Dr. Reginald Webster. The factor of financial loss is not so clearly recognized. Two statements should suffice to give the necessary emphasis. The first is that, as quoted by Lieut.-Colonel Cooper, the cost in pensions and treatment of tuberculous soldiers of the First A.I.F. (1914–18) amounted in 1938 to approximately half a million pounds. The second is that the Department of Repatriation has found that in Australia in the last war the average cost of each ex-soldier with pulmonary tuberculosis has approximated £3,000. These figures should make clear the saving in cost by the sifting out of tuberculous recruits. It should be noted, too, that in addition to those cases developing active tuberculosis, repatriation experience has shown that many, if not all, of those soldiers with latent lesions who have developed pulmonary symptoms of any kind in the succeeding years have been regarded as eligible for treatment and pension.

Criticism of the Method of Miniature Radiography

Criticisms have fallen under two main headings—medical and administrative: (1) that the method of miniature radiography is not accurate enough, and that cases will be missed; (2) that because of delay in recruiting the method is impracticable as an Army measure.

1 (*a*). *That Recruits with Tuberculosis are Missed.*—While it is at once admitted that the miniature film is *not* as good as the full-size film and will not pick up 100% of early lesions, the degree of accuracy reached by experienced observers is very striking. Subsequent personal comparison of several hundred 14 by 17 inch films has inspired admiration for the "spotting" ability of the teams examining the miniature films. But occasional failure to recognize an early lesion would not seriously detract from the value of a method which has so

efficiently sifted out such a large number of cases. Three other methods of routine radiographic examination have been advocated by critics of the miniature films. These are:

(i) *Fluoroscopy.*—The time consumed is great and there is no permanent record—an important point in regard to the question of pensions.

(ii) *Use of the Full-size Film.*—The expense of this method is very high and much more time is required for taking, developing, and viewing the film.

(iii) *Use of the 5 by 4 inch Film.*—This eventually may be the method of choice, although a recent demonstration arranged in Melbourne by the Watson Victor *X*-Ray Company, in which miniature, 5 by 4 inch, and 14 by 17 inch films were compared, did not demonstrate any appreciable margin of superiority of the 5 by 4 inch film over the miniature film. Most of us who saw the demonstration preferred the miniature film.

Edwards (1940) complains that claims have been made that the question of the activity of a lesion can be decided on the miniature film. Lieut.-Colonel Cooper in his article clearly states that "the activity of a tuberculous lesion can rarely be determined upon a small film alone." In the Australian Army any attempt at radiological diagnosis of activity is made on examination of the subsequent 14 by 17 inch film. The basis function of the miniature film is to reduce the number of large films necessary. The criticism by Brailsford (1940) that many cases of pulmonary tuberculosis are detectable by clinical methods at a stage where there is no radiological evidence, although not a criticism of the miniature method, should be mentioned. D'Arcy Hart (1940), in reply, has inquired where such a series of cases has been published. Dr. Reginald Webster's observation of the finding of tubercle bacilli in three cases from which radiological evidence and clinical evidence were absent does, however, give cause for reflection and for further investigation. On the other hand, few clinicians experienced in tuberculosis would claim that any large number of recruits with clinical tuberculosis will have a completely normal chest radiograph.

1 (*b*). *That Non-tuberculous Recruits are Diagnosed as Tuberculous.*—Every recruit rejected as the result of *x*-ray examination is referred to the civil tuberculosis department for full investigation and treatment if necessary. Here the diagnosis is reviewed, and there is ample time for investigation and observation. This eliminates the possibility of wrongly labelling a man tuberculous.

2. *That Routine Radiography of Recruits is Impracticable because of the Delay occasioned in Recruiting.*—The report of the committee appointed by the Minister of Labour and National Service under the chairmanship of Lord Horder (1940), while expressing its opinion that the adoption of the method of miniature radiography represents the ideal to be aimed at in the medical examination of the armed Forces, stated that it is impracticable at the present time "because of lack of apparatus, lack of sufficient numbers of expert examiners, and because the inclusion of this form of examination would seriously delay the medical examination of recruits." Unremitting perseverance by a small group of enthusiasts, headed by Lieut.-Colonel Cooper and strongly supported by the Director-General of Medical Services, has in Australia overcome these very real difficulties. The Army now possesses ten units for miniature radiography, one of which forms a mobile unit in a train and travels great distances in Queensland. The whole of this apparatus, with the exception of *x*-ray tube, timer, and camera, has been manufactured in Australia. A team of keen experts has been gathered in each city, and there has been no hold-up of recruiting. Results of miniature films are available in as short a period as six hours. The maximum period allowed for obtaining results of miniature films is thirty-six hours. Approximately 97% of recruits can leave the recruit reception depot on receipt of this result. The other 3%, for whom large films have been ordered, have these taken immediately. The results are available within twenty-four hours, and the men are at once brought before the Specialist Board. Finality in regard to suspects is therefore reached within three days, and in most cases within a maximum period of seven days. Only occasionally is it found necessary to await the result of cultural tests. Details of procedure are given in Appendix III. The fact that the method has now been adopted by the Royal Australian Navy and the Royal Australian Air Force demonstrates its practicability. In both these services the result of several thousand radiological examinations shows approximately the same incidence rate of active tuberculosis as in the Australian Army—that is, about 1 in 200. Recently authority has been granted to carry out a radiological chest survey of internees in Australia.

Summary

More than 100,000 recruits of the Australian Imperial Forces have been subjected to routine chest *x*-ray examination by the method of miniature radiography.

One in every 100 has shown radiological evidence of active or latent tuberculosis, and 1 in every 200 of active tuberculosis.

The diagnosis of tuberculous infection has in a large number of cases been substantiated by bacteriological investigation, the results of which are given in this issue in a report by Dr. Reginald Webster.

A considerable number of instances of non-tuberculous pulmonary pathology and of cardiac and vascular lesions have been observed.

The results here given represent simply a summary of a very great deal of work done by members of the A.A.M.C., including medical officers, technicians, and staff, throughout Australia. The opportunity is appreciated of being able to acknowledge the enthusiasm and efficiency with which this work of considerable national importance has been carried out in every command in the Commonwealth. Valuable co-operation has been given by Stamford *X*-Ray Company and Watson Victor *X*-Ray Company.

APPENDIX I

Results of Analysis

Recruits examined by miniature radiography	Over 100,000
No. of 14 by 17 inch films ordered	2.74%
No. of films showing evidence in lung fields of past or present tuberculous infection of the secondary adult type of tuberculosis	1.04%
No. of recruits showing radiological evidence of active pulmonary tuberculosis	0.56%
No. of recruits showing fibrotic or calcified areas in the lung field suggesting a healed or quiescent lesion	0.47%
No. of recruits showing radiological evidence of non-tuberculous pulmonary pathology	0.25%
No. of recruits showing radiological evidence of cardiac or vascular lesions	0.12%

APPENDIX II

The Unit for Miniature Radiography

This remains substantially as it was described by Lieut.-Colonel Cooper in Appendix I of his original article. An improved Contax camera is now used. This is fitted with an f/1.5 lens and auxiliary lens. The latter permits accurate focusing at the short screen-film distance and is mounted on a special adjustable mounting-plate. The camera has been altered to provide locking facilities on both the lens aperture and the lens focus. Operation of the shutter has been eliminated, the shutter remaining open at all times, and the film being merely wound on one complete frame after each exposure has been made. The camera case has been supplied with a special mounting-plate, arranged for easy removal or fitting. The construction of the mounting assembly is such that there is no necessity to re-focus the camera at any time.

Experience over the past twelve months has brought about a definite improvement in the quality of the end-results, mainly due to two factors:

(*a*) Improved dark-room processing technique of the Super XX film.

(*b*) Improved projection facilities. Experience has shown that the image is best projected with a projector of the

400-watt type on to a screen made of a sheet of matt-surface bromide photographic paper which has been fixed, and of a projection-screen size not exceeding 10 by 12 inches, framed with a flat black mask, thus eliminating unwanted reflection from the edges of the projection screen. It is sometimes found helpful to view doubtful lesions through opera-glasses.

It is anticipated that film manufacturers will specially develop a film for miniature radiography with the object of increasing the speed of the emulsion to the particular luminosity given off by the fluorescent screen and of providing greater contrast in the image recorded on the photographic emulsion. Lag in the fluorescent screen has no detrimental effect, and in fact enables the actual exposure time to be reduced. For miniature radiography the apparatus is operated at 50 mA 85 kV, with exposure times in the order of 0.5 second.

Tube and maintenance costs have been comparatively minor items, due, we believe, to the fact that excessive milliamperages that could not safely be used when operating at high speed even with fully rectified equipment have not been employed. Little alteration has been found necessary in the clerical and radiographic procedure originally adopted. At some centres where line conditions are not ideal, the fitting of a constant current stabilizer ensures greater uniform density in resulting miniatures, and provides a further safeguard against tube overload.

APPENDIX III

Procedure Employed

In the main this is as laid down in Appendix II of Lieut.-Colonel Cooper's original paper. In order to bring the result of the chest radiograph into the same category as the blood group and the results of vaccination and inoculation, steps are being taken to have an appropriate entry recorded in each soldier's pay book.

The following is a summary of the procedure in regard to each recruit:

1. On completion of the ordinary medical examination, which is a very thorough one, the applicant goes into an adjoining room and has the chest radiograph taken on the unit for miniature radiography.

2. All miniature films taken up to 3 p.m. are examined on the same evening by the Viewing Committee, consisting of at least one radiologist and one physician. Films taken after 3 p.m. are viewed the following evening.

3. Recruits are paraded next morning. Those whose films are regarded as beyond suspicion are drafted to units. If any abnormality is detected, or there is a reasonable doubt, a 14 by 17 inch film is at once taken. Approximately 3% of recruits have the large films taken. This film is examined by the Viewing Committee the same day.

4. Those who have had 14 by 17 inch films taken are paraded either on the second day or the third morning. If the film has been passed enlistment proceeds. If not, the man is examined by a Specialist Board appointed for this purpose and consisting of one consulting physician interested in tuberculosis and one specialist in tuberculosis. This examination is in most cases carried out at once. If it has to be deferred the man is drafted to accommodation reserved for this purpose in a camp hospital. The acceptance or rejection of the recruit depends not on the radiological report but on the opinion of this Specialist Board, which reviews the history, the clinical and radiological findings, and in some cases the bacteriological results. If rejected the man is placed under the care of the State Department of Tuberculosis, and his name is notified to this department.

5. In a large number of instances it has been possible to have a complete bacteriological investigation carried out, including culture of sputum or gastric contents.

BACTERIOLOGICAL EXAMINATIONS SUPPLEMENTING THE RADIOLOGICAL SURVEY OF THE AUSTRALIAN IMPERIAL FORCE

PRELIMINARY REPORT

BY

REGINALD WEBSTER, M.D., D.Sc., F.R.A.C.P.

Honorary Major, Australian Army Medical Corps Reserve; Pathologist to the Children's Hospital, Melbourne

The present report is published with the approval of the National Health and Medical Research Council of Australia, and at the suggestion of the Director-General of Medical Services, Major-General R. M. Downes, who from the moment of his authorization of the work has followed its progress with a lively and sympathetic interest.

Scope and Objective

In the detection of pulmonary tuberculosis the ultimate and only unequivocal proof is the demonstration of the tubercle bacillus: the necessity for providing bacteriological confirmation of radiological diagnosis whenever possible requires no emphasis.

Many accounts of mass radiological surveys have appeared within recent years, but in the few in which bacteriological findings are mentioned such reference is limited to a statement that a certain proportion of the subjects of the *x*-ray investigation exhibited a "positive sputum." By this term it is generally to be understood that tubercle bacilli are brought into evidence by the microscopical search of films: but as a means of sifting sputum and other pathological exudates for tubercle bacilli microscopical search is a sieve of very coarse mesh. It has been computed by H. J. Corper (1928) that tubercle bacilli are not detectable in smears until their numbers reach 100,000 per c.cm., whereas guinea-pig inoculation and appropriate methods of cultivation will disclose them in numbers as few as 10 to 100 per c.cm.

To the best of my knowledge the relevant literature contains no record of a large-scale radiological survey supplemented by a concurrent and carefully planned bacteriological investigation of the scope and character which it is the purpose of this report to indicate.

The systematic radiological examination of the entire personnel of the Second Australian Imperial Force, carried out under military discipline, created an opportunity, unprecedented in Australia, of instituting an important and far-reaching public health research. If parallel bacteriological work could be sustained it held promise of providing data upon which to assess the accuracy of microradiographic diagnosis, of being of immediate practical assistance to medical boards, and of elucidating facts regarding the existence and number of "carriers" of the tubercle bacillus among a large and presumed healthy section of the population. This phase of the investigation assumed prime importance when considered in relation to proposals for the eventual extension of thoracic radiography to the civilian community.

In planning the work from the laboratory aspect it was realized that there would be few opportunities of repeating the bacteriological examination for any individual soldier. Both the magnitude of the undertaking and the necessity for working within Army requirements for prompt disposal of the men precluded, in the great majority of instances, more than one attempt to establish the diagnosis of pulmonary tuberculosis on an incontestable bacteriological basis. In view of the serious

limitations of direct microscopy of smears of sputum, provision was made to subject to cultivation by methods appropriate to the growth of *B. tuberculosis* all specimens of sputum in which the search by microscope should fail. It was further designed that, should sputum be unobtainable, identical procedures would be adopted with the mucus aspirated from the fasting stomach.

Principles

Experience during the past three years in the examination of 1,270 diverse samples of pathological material suspected of a tuberculous origin has convinced me of the reliability and sensitivity of a proper technique for the cultivation of tubercle bacilli and of the inadequacy of the film method. Shrewsbury and Barson (1937) of the University of Birmingham showed that the method of culture employed by them yielded 100% of successful cultures of the tubercle bacillus from a diversity of specimens comprising sputum, cerebrospinal fluid, urine, faeces, and pus. The same workers demonstrated that of 135 samples of sputum in which tubercle bacilli could not be detected microscopically 29 (21.4%) were tuberculous by cultural examination. Similar findings have been recorded by C. A. Green (1938) from the bacteriological department of the University of Edinburgh. Green reported that in the examination of 2,796 specimens of sputum for the presence of tubercle bacilli the positive findings by cultivation exceeded those attending the microscopical examination of films by nearly one-third (32.4%). More striking perhaps in this particular are the figures of Corper and Cohn (1933), who have published results of a routine cultural examination for tubercle bacilli of sputa in which the organisms could not be detected by microscopical search. Of 100 samples of sputum, in which "negative" results were consistently obtained in monthly examinations of film preparations over periods ranging from four months to two years, no fewer than fifty yielded a "positive" finding by a single cultural test.

The significance of such findings as a compelling indication for the adoption of routine culture of sputa under suspicion as tuberculous is obvious, and for the purpose and under the conditions of the research relating to the Second A.I.F. systematized cultivation of sputum and/or gastric mucus was imperative.

The demonstration of tubercle bacilli in the mucus aspirated from the fasting stomach has long been familiar in paediatric practice, forty-one years having elapsed since Meunier first introduced the method to overcome the difficulty occasioned by the fact that children invariably swallow rather than expectorate sputum. Meunier's work did not attract the attention it undoubtedly merited until it was applied by Armand Delille and Vibert in 1927. Since that year a number of workers in the field of paediatrics—notably Wallgren in Sweden, Poulsen in Denmark, and Collis and Brockington in England—have established the method as one of very great clinical value.

Influenced by the fact that many specimens of so-called sputum do not represent mucus of bronchial origin, and that many persons excrete small amounts of bronchial mucus which they swallow rather than expectorate, a number of Continental workers, led by Armand Delille, Lestocquoy, and Vibert (1930), have applied Meunier's principle to the examination of adults. In England they have been followed by Kayne and Hounslow (1939), whose work represents the only attempt so far recorded on the part of English workers to extend to adult practice a technique which has yielded such striking results among children. Kayne and Hounslow have reported findings in which by cultural and animal inoculation methods tubercle bacilli were shown to be present in the gastric content of 17 out of 55 sanatorium patients who either produced no sputum or provided specimens in which both direct and cultural methods of examination failed to detect tubercle bacilli.

Arresting evidence of the importance of directing attention to the contents of the fasting stomach in the endeavour to obtain bacteriological confirmation of radiological indications of pulmonary tuberculosis is furnished by the work of R. H. Stiehm (1939), Director of the Department of Student Health in the University of Wisconsin. Stiehm assembled 50 students in whom radiological findings denoted the presence of what he termed "minimal" pulmonary lesions. In none of the group was there any clinical evidence of tuberculosis; all of the students regarded themselves as well, and in such samples of sputum as they could produce the tubercle bacillus could not be demonstrated. The next step was to subject each student to aspiration of the contents of the fasting stomach on three successive mornings in order to examine the product for the presence of tubercle bacilli by microscopical search and animal inoculation. Acid-fast bacilli were found in films of gastric mucus in 9 of the 50 students, but in no fewer than 36 (72%) tubercle bacilli were revealed in the gastric content by guinea-pig inoculation. In 36 instances, therefore, the radiological findings were endorsed and the presence of an unhealed tuberculous lesion was unequivocally demonstrated.

Procedure and Standards

With the imprimatur of the Director-General of Medical Services, Major-General R. M. Downes, and the co-operation of the Deputy Director of Medical Services, Southern Command, Colonel C. Gordon Shaw, a routine has been established in Victoria by which recruits who display radiological evidence of pulmonary tuberculosis are sent to the Camp Hospital, Broadmeadows, whence they are paraded in batches of four, six, or eight a day at the Children's Hospital laboratory. The men arrive at 9 a.m., having had no food or drink since the previous evening. Those who can expectorate a specimen which can be approved as genuine bronchial mucus are excused the passage of a Rehfuss tube, but it was to be anticipated that many of these apparently healthy young men would be unable to produce any sputum. In dealing with such the routine is to aspirate the contents of the fasting stomach, and the men have co-operated extremely well in the swallowing of the Rehfuss tube.

It is considered very important that the men should present themselves in person and not send in samples of sputum. By the latter procedure many unsatisfactory and salivary specimens would be received; there is also the risk of substitution of specimens. With the man in attendance the specimen of sputum can be approved or otherwise, and in the latter event a sample of the contents of the fasting stomach secured.

The standards adopted in the Army bacteriological examinations are as follows:

1. If acid-fast bacilli are demonstrable in direct Ziehl-Neelsen preparations from sputum a "positive" bacteriological finding is returned.

2. If an acid-fast bacillus of the requisite cultural characters is cultivated from the sputum of a man designated radiologically "active" it is accepted as *B. tuberculosis*.

3. If the acid-fast bacillus is recovered from the sputum of a man designated radiologically as the subject of old, healed, inactive, or doubtful pulmonary tuberculosis, such acid-fast bacillus is required to produce progressive tuber-

culosis in a guinea-pig before final acceptance. In the meantime a report of a "strong presumption" of active pulmonary tuberculosis is issued.

4. In every instance in which the acid-fast bacillus is cultivated from the gastric mucus, irrespective of the character of the radiological report, the virulence of the culture for the guinea-pig is determined. This is rendered necessary by the occasional occurrence of saprophytic acid-fast bacilli, some of which, particularly those of "rough" cultural characters, closely resemble true tubercle bacilli. Again an interim report of "strong presumption" of active tuberculosis is issued.

Progress Results

In this investigation, so far, the number of men for whom examinations are complete to date is 322. In the early stages of the work a number of men (51) were sent for examination in error; for although all were rejected or deferred by the radiologists, such action was based on grounds other than that of pulmonary tuberculosis. The intrathoracic pathological states disclosed by *x*-ray examination of the men in this group included such conditions as congenital pulmonary cysts, hydatid cysts of the lung, mediastinal tumour, probable pulmonary neoplasm, abnormal cardiac shadows, and varying degrees of dilatation of the aorta. That a little confusion should have occurred in the beginning is a circumstance not altogether to be regretted, for these men furnish an interesting control group. From only one man of the 51 was an acid-fast bacillus recovered by culture; the source of the culture was gastric mucus, and the organism was eventually shown to be non-virulent to a guinea-pig.

Eliminating 51, therefore, as never having been radiologically suspect as regards pulmonary tuberculosis, the number of men rejected or deferred by reason of *x*-ray evidence of pulmonary tuberculosis, and in whom bacteriological examination was undertaken, was 271. Of these, 100 (36.9%) were shown to be actively discharging tubercle bacilli. The manner in which the positive bacteriological findings were determined in the 100 cases was by direct smear examination of sputum, 32; by culture from sputum in which tubercle bacilli could not be detected by microscopical search, 46; by culture from the gastric mucus of men from whom no sputum was obtainable, 22.

The application of cultural methods and the utilization of gastric contents in the absence of sputum have therefore resulted in 100 positive findings, as against the 32 which would have been the number had the examinations been restricted to smears of sputum. The average reporting time for sputum cultures was 18.6 days, and the average for gastric mucus cultures 21.6 days.

Commentary

That the figure for positive results obtained by the microscopical examination of smears of sputum (32) compares so unfavourably with that attending sputum cultures (46) cannot be attributed to hurried or inadequate scrutiny. Considerations of economy of effort and culture medium, and the possibility of summary disposal of the specimen with an immediate positive report, were strong inducements to persevere in the search for acid-fast bacilli in the films.

The method of cultivation applied throughout has been the sulphuric acid technique of Lowenstein, and the culture medium chosen that of Petragnani as modified by S. Russell Jamieson (1936). At least three culture tubes have been prepared from every specimen of sputum or gastric mucus, and six tubes of medium have often been expended on one individual.

The positive findings attending cultivation from the gastric mucus (22) have all been verified by virulence tests and by proof of the ability of the cultures to induce progressive, widespread, and fatal tuberculosis in guinea-pigs. It is of interest to note that in eight men acid-fast bacilli, subsequently shown by cultivation and guinea-pig inoculation to be virulent tubercle bacilli, were detected by the microscopical examination of direct smears of the gastric mucus.

There were seven instances of cultivation of acid-fast bacilli from the gastric contents not included in the above statement of results. Three were omitted because the men who provided them had already been included in the group confirmed bacteriologically by the detection of tubercle bacilli in film preparations of the sputum. Of the remaining four, two were non-virulent to guinea-pigs, and in two the virulence remained undetermined owing to the late appearance of contaminants in cultures which were perforce neglected for some time owing to pressure of work.

Of the 100 men in whom bacteriological proof of active tuberculosis has been adduced so far, 54 maintained negative answers to specific questions regarding haemoptysis, pleurisy, sanatorium treatment, and the occurrence of pulmonary tuberculosis among their near relatives. A few spoke lightly of a "cigarette cough," while many declared that, childish illnesses excluded, they had never had occasion to consult a doctor and had never lost a day's work. Affirmative replies with respect to one or more points in the cross-examination indicated above were received from the remaining 46 men. Eight had experienced haemoptysis and 16 had suffered an attack of genuine pleurisy. Two were obviously ill when they were presented for bacteriological examination. No fewer than 10 had formerly been inmates of sanatoria, and 17 confessed to the occurrence of pulmonary tuberculosis in their own families or among their near relatives. Such information was no doubt suppressed by these men at the time of their enlistment and preliminary medical examinations, but with the realization that they had been weighed in the radiological balance and found wanting they evidently felt that they could gain nothing by further concealing the facts of their clinical histories.

Correlation of Radiological and Bacteriological Findings

It is laid down as routine procedure in the radiological survey of the Australian Military Forces that every man concerning whom suspicion is raised by the miniature screen photograph shall be re-examined by the standard 14 by 17 inch radiograph. The radiological reports upon which the following correlation of *x*-ray and laboratory findings is based are those issued as interpreting the large films.

Group I

In a group of 152 men in whom the radiograph was regarded as indicative of *active* pulmonary tuberculosis the number of positive bacteriological findings was 83 (54.6%).

Group II

Among 90 men designated radiologically as subjects of old, healed, inactive, or doubtful tuberculosis there were 10 (11.1%) positive bacteriological results. *B. tuberculosis* was recovered by culture from the sputum of 6 of the men in Group II, by gastric mucus culture in 3, and in the case of the tenth man acid-fast bacilli were found in a Ziehl-Neelsen preparation of the sputum. All six sputum cultures, as also the three gastric mucus cultures, induced severe and fatal tuberculous lesions in

guinea-pigs. The following table supplies some details of this interesting group:

Serial No.	X-ray Report	Bacteriological Report	History
37	Scattered calcification; right apex	Positive gastric culture	Pain in chest 15 months ago; did not go to bed. Otherwise had always been well
73	Evidence of old Tb. infection in the lungs; nothing suggesting anything recent	Positive sputum culture	Haemoptysis; sanatorium treatment; fistula in ano
137	Suspicious area in right infraclavicular region, radiating from hilum. Defer	Positive gastric culture	Clear personal and family history
167	Small calcified nodules in apex of left upper lobe. No evidence of activity, and remainder of lungs normal	Positive sputum culture	Three years in sanatoria. "Short of breath"
225	Small calcified nodules at left apex. No definite evidence of activity	,,	"Dry" pleurisy 15 years ago; was not laid up. Otherwise always well
247	Localized Tb. infiltration at left apex; one very small nodule in first interspace area; a little calcification evident. Suggest bacteriological examination	,,	Haemoptysis in 1930. Sanatorium for five months in 1932. Father died of pulmonary Tb.
250	Very slight Tb. lesions; both apices Partly calcified. Suggest bacteriological examination	,,	Personal and family history clear
251	Slight infiltration in apical region of right upper lobe. Left lower probably Tb. Suggest bacteriological examination	,,	Suspected of pulmonary Tb. in 1939. Sister died of phthisis
302	All tuberculous lesions of right upper lobe quiescent. For bacteriological examination	Positive gastric culture	Served in war of 1914–18. "Pulmonary fibrosis"
307	Exaggerated lung markings in right chest. ? upper respiratory infection and delayed resolution of acute process	Acid-fast bacilli in smear of sputum	Clinical and family history clear

It may fairly be represented that although the figure for the proportion of bacteriological confirmations of x-ray diagnosis is high, particularly in Group I, in which it reached 54% among 152 men designated subjects of active pulmonary tuberculosis on radiological evidence, it is of necessity an under-estimate. As has been indicated, the men pass the laboratory way but once, and it is only in exceptional instances that repeat examinations are feasible. Were it possible again to comb through those men for whom a negative bacteriological finding has been recorded it is more than probable that the tubercle bacillus would be uncovered in some of them.

Group III

There remain three men to be placed in a third group because no x-ray evidence of pulmonary tuberculosis was apparent.

Serial No.	X-ray Report	Bacteriological Report	History
238	Lungs clear; pass	Positive sputum culture	Father died of pulmonary Tb. 12 months ago. Two cousins have been in sanatoria
253	Pass	,,	Pleurisy 4 months ago. Brother rejected as active Tb.
255	No sign Tb.: pass	Positive gastric culture	Personal and family history clear

That the above three cultures were those of genuine and virulent tubercle bacilli was proved in each instance by guinea-pig inoculation.

In the case of No. 253 it has been ascertained that he was sent for examination in mistake for his brother, who was summarily rejected by the radiologists. No. 253, however, gave a history of pleurisy, and from a second sample of sputum acid-fast bacilli were again cultivated. That No. 238 and No. 255 presented themselves for bacteriological examination must have been fortuitous in view of the x-ray reports with regard to them, and three such unanticipated bacteriological results are startling, and are provocative of reflection.

Conclusion

The work will be continued in 1941, and the present communication, as a preliminary report, is limited to a statement of objectives, underlying principles, methods, and progress results. Temptation to comment on the vexed question of the radiological estimation of activity, and to discuss risks of error due to the appearance of chromogenic acid-fast bacilli other than true tubercle bacilli in cultures, must be resisted in view of wartime exigency regarding space.

It is submitted, however, that the results obtained to date establish beyond criticism the prescience of the policy which instituted the radiological survey of the Second Australian Imperial Force.

The work which I have endeavoured to outline is sponsored by the National Health and Medical Research Council of Australia, by whom a research grant has been allotted for its continuance.

I have already expressed appreciation of the encouraging interest of Major-General R. M. Downes and the cordial co-operation of Colonel C. Gordon Shaw. Other officers who have done much to facilitate the inquiry are Lieut.-Colonel E. L. Cooper, Lieut.-Colonel L. M. Routh, Major Douglas Galbraith, and Captain N. T. Bull. As Officer-in-Charge, X-ray Department, Southern Command, Captain Bull has maintained a happy liaison between the x-ray service and the bacteriological laboratory. My technical assistant, Mr. H. Weir, is bringing to the work an enthusiasm and a devotion to duty which are beyond praise.

THE BLOOD PLATELETS AND SPLENIC EXTRACTS

BY

G. M. WATSON

(*From the Nuffield Department of Clinical Medicine, Ox*

In 1938 Troland and Lee reported the presence of platelet-reducing principle in acetone extracts of spl from patients with thrombopenic purpura; when gi intravenously to rabbits these extracts lowered the co of the circulating platelets. Torrioli and Puddu (19 then drew attention to earlier work by themselves a others in this field. They had found that aqueous extr both of normal spleens and of spleens from patients w thrombopenic purpura contained a factor which capable of inhibiting the development of megakaryocy when given in small doses but damaged them in lar doses. These workers also succeeded in producing a f in the circulating platelets in the rabbit by intraveno injection of an aqueous extract of a normal spleen.

Several workers have attempted to confirm the resu obtained by Troland and Lee. Major and Weber (19 obtained negative results with two spleens from cases thrombopenic purpura. Pohle and Meyer (1939) m spleen extracts from three cases of thrombopenic purp with completely negative results. Using spleens from t such cases, Hodge and Strong (1939) were equally unsu cessful. All these workers used acetone extracts. Hob and Witts (1940) obtained a fall of platelets in the rab with an acetone extract of the spleen from one case thrombopenic purpura. They also prepared acetone

saline extracts of normal spleens: the acetone extract was inactive, but the saline extract reduced the platelet count when given intravenously in a large dose.

Rubegni (1940) discusses the work of Defrise, who modified the technique of Troland and Lee by a further extraction with ether and obtained positive results with the spleen removed from an ill-defined case of haemorrhagic disease. Rubegni made acetone extracts from fresh calf's spleen, liver, and muscle, and administered them intravenously to rabbits. The splenic extracts produced in most cases a fall in platelet count of about 50%; the liver extracts were also followed by a decrease in platelets, though less than that produced by the splenic extracts; muscle extracts caused no change. Rubegni did not succeed in keeping a rabbit's platelets low by repeated injections, though this had been done by Troland and Lee.

It appears from the literature that the platelets of the rabbit may fall when extracts of spleen are administered intravenously. This effect is inconstant, and it is by no means limited to spleens obtained from patients with thrombopenic purpura; it may also occur with extracts of normal spleens and liver.

Experimental Methods

The objects of the following experiments were, first, to compare the effect of different types of extract of the spleen and the tissues used as controls; and, secondly, to see if any depression of the platelets resulted if the injections were not given intravenously.

Extracts were made from post-mortem material, sheep spleens removed directly after killing, and three spleens removed at operation from patients with thrombopenic purpura. Acetone extracts were prepared as described by Troland and Lee, and alcohol extracts by a similar technique. Saline or aqueous extracts were made by mincing the spleen and extracting in the cold for twenty-four or forty-eight hours, then centrifuging. When saline extracts were kept several days for repeated injections they were covered with toluene and shaken periodically. These extracts were usually made up so that 1 c.cm. of the final extract corresponded roughly to 1 gramme of spleen. Another extract was prepared by treating finely minced spleen with anhydrous sodium sulphate at 37° C., separating the supernatant fluid, and then removing as much of the sodium sulphate as possible; 170 grammes of spleen was used, and the resulting extract, made up to 5 c.cm., was given to one rat. Pressed juice from spleen was also tried. Another spleen was allowed to autolyse under toluene; but this preparation was too toxic, and the rats receiving it died.

The extracts have in most cases been given by the intraperitoneal route to rats, the rest intravenously to rabbits. The rats weighed 0.3 to 0.4 kg. and the rabbits about 1.5 kg. The platelet counts were made by a direct method (Lempert, 1935). Counts were made on the day before injection, again immediately before injection, and then several times in the twenty-four hours following injection; none of the changes observed persisted more than twenty-four hours. Rat platelet counts usually gave figures between 500,000 and 900,000 per c.mm. in blood obtained from the tail after warming. With rabbits the counts were lower. In all, 56 rats and 14 rabbits received injections, the animals being used once only. As controls, pairs of rats were given intraperitoneal injections of 10 c.cm. of sterile Ringer-Locke solution, a 10% suspension of human red cells, and a saline extract of muscle; the rats receiving Ringer's solution showed a rise in platelets of 15%, the others no change or a slight fall. The degree of accuracy in counting is not high, and I do not regard alterations of the order of 20% as having much significance.

Extracts of Normal Spleen

Six rats received acetone extracts of human spleen, the dose varying from 5 to 15 c.cm. The greatest subsequent change from the level just before injection was a fall of 35%, but in another rat a larger dose of the same extract caused no reduction in platelets. The other injections were followed by falls of 16% or less.

Six rats received alcoholic extracts of human spleen in doses of 5 to 15 c.cm. The extract given to two of them was toxic, and they died; injection of the other extract was followed by changes in the platelet count varying from a rise of 11% to a fall of 28%, without relation to the size of the dose.

Six rats were given Ringer's extract of normal human spleen in doses of 5 to 15 c.cm. Here the changes in platelet count varied from an increase of 12% to a decrease of 25%, independently of the dose.

Four rats were given 10 to 15 c.cm. of an aqueous extract prepared from a human spleen dehydrated with alcohol, dried, and powdered before extraction. There was no effect on the platelet count. Two rats were given 10 c.cm. of saline extract of fresh sheep spleen without effect on the platelets. Two more rats received 10 c.cm. of pressed spleen juice: no change resulted in one; the other showed a rise of 17%. The sodium sulphate extract did not alter the platelet count.

In order to determine whether repeated injections might depress the platelet count, one group of 6 rats received four injections, each of 10 c.cm., of saline extract of fresh sheep spleen, given over a period of nine days. Platelet counts were made on the day before the first injection, several times during the course, and for two days after the last injection. Only one rat showed any appreciable change, and that was a transient elevation of 40%. Four other rats received repeated injections of acetone extract of fresh sheep spleen, counts being made in the same way. No significant changes were observed.

Extracts given Intravenously

Normal saline extracts of muscle, liver, and sheep spleen were given intravenously to rabbits in 20-c.cm. doses. Two rabbits receiving splenic extract showed falls of 27 and 29%; two receiving liver extract showed falls of 25 and 38%; muscle extract caused a fall of 50%.

Extracts of Thrombopenic Spleens

Three such spleens were available. The first was from a woman of 27 with purpura of acute onset, characterized by severe haemorrhage, a greatly prolonged bleeding-time, and a platelet count below 10,000. No drug or medicine had been taken by the patient. The other two spleens were from chronic cases of the disease, one being removed during an interval and the other during an active phase. Each spleen was divided into halves, and acetone and saline extracts were prepared. The residue from the saline extract was subjected to further extraction with alcohol. These extracts were prepared aseptically, and each was injected into both rats and rabbits.

When given to rats intraperitoneally in 10-c.cm. doses none of the extracts caused any significant change in the platelet count. One rat received four injections of a saline extract on alternative days without a decrease in platelets. The acetone extracts were given intravenously to rabbits in doses of 25 to 45 c.cm. and caused falls of 15 to 35% in the platelet count; in the same doses the saline extracts produced falls of 23 to 28%. In all cases the falls appeared within a few hours of injection and the counts had returned to their previous level within twenty-four hours.

Discussion

These results show that none of the extracts tested, whether from normal spleen or thrombopenic spleen, contains a thrombopenic principle in quantity sufficient to be demonstrated by intraperitoneal injection into rats. The occasional falls recorded are not large enough to be significant and did not occur in other rats receiving the same extract. Repeated injections have been no more successful in reducing the platelet count. When the extracts were given intravenously to rabbits the results were rather different. Some lowering of the platelet count was produced by all the extracts used—the least by an acetone extract of thrombopenic spleen, the greatest by a saline extract of muscle. This suggests that tissue extracts given intravenously may lower the platelet count, but it does not support the view that there is a specific thrombopenic factor in splenic extracts.

All the reports dealing with the existence of such a factor, except those of Torrioli and Puddu (1934) on its effect on the megakaryocyte in marrow culture, are based on the results of intravenous injection. Many non-specific agents—for example, heterologous red cells or serum, peptone, and suspensions of micro-organisms or inert particles—are capable of causing a considerable reduction in platelets when given intravenously (Tocantins, 1938), and there is no reason why these comparatively crude extracts of the spleen should be put in a special category. It is also worth noting that a splenic extract has been reported as causing a thrombocytosis when given subcutaneously (Haenlein and Schliephake, 1935) and that an anti-spleen serum produces thrombopenia (Bedson and Johnston, 1925). The evidence for the existence of a specific thrombopenic principle in splenic extracts is therefore unconvincing.

Summary

A series of extracts from normal spleens and from three cases of thrombopenic purpura have been prepared, and were injected into rats and rabbits. No evidence of the existence of a specific thrombopenic factor was found, and it is suggested that the positive results of a few others workers may have been due to non-specific reactions to intravenous injections.

I wish to thank Dr. H. Scarborough of the Edinburgh Royal Infirmary for supplying material and case records, and Prof. L. J. Witts for his criticism and advice.

EVALUATION OF HYSTERICAL SYMPTOMS IN SERVICE PATIENTS

BY

W. P. MALLINSON, B.M., M.R.C.P.

Temporary Surgeon Lieutenant-Commander, R.N.V.R., Neuro-psychiatric Specialist; late Assistant Medical Officer at the Maudsley Hospital

Since the outbreak of war the Navy has been working under conditions of continuously severe stress, and the personnel has been increased by the introduction of many conscripted recruits. Mainly among these men, and among reservists recalled from their civilian jobs and from home life to the rigorous conditions of the Service in wartime, a certain number of hysterical reactions have inevitably occurred. It has already been shown, both in the last war (Beaton, 1920) and in this (Curran and Mallinson, 1941), that the incidence of hysteria as a primary diagnosis is not high in naval psychiatry.

The committee on head injuries of the Medical Research Council (private information, unpublished) has defined hysteria as "a condition in which mental and physical symptoms not of organic origin are produced and maintained by motives never fully conscious, directed at some real or fancied gain to be derived from these symptoms." In addition to a definition it is necessary, for clinical purposes, to have criteria which will help to reduce the very varied manifestations of hysteria to an ordered symptomatology, to minimize subjective and impressionistic judgments, and to cut short philosophical speculation about fully and incompletely conscious motives. The Services make demands on their medical officers which call for special criteria of prognosis and recovery. The disappearance of symptoms is not enough; a reasonable assurance of future reliability and freedom from relapse under war stress is required. If this assurance cannot be given, discharge from the Service is called for, even though recovery may be adequate from the point of view of civilian life. It must also be remembered that a successful hysterical "escape," if the motive is even dimly present in consciousness, will permanently reduce the social efficiency of the individual by facilitating a recurrence in the face of subsequent difficulties, and within the Service it will impair morale by inviting imitation by others.

The long and unbroken period of active service which the Navy has undergone is offered as the reason for giving a short account of a classification, derived from clinical and aetiological considerations, which has been found of practical value in the treatment and disposal of patients showing a hysterical reaction. On discharge from hospital a patient may (i) return to full duty, (ii) return to modified duty in accordance with psychiatric advice, or (iii) be invalided from the Service. The reactions are classified as follows: (1) simple hysterical dissociation; (2) hysterical *prolongation*; (3) hysterical *exaggeration*; (4) hysterical simulation; (5) hysterical "complications" of an underlying disorder.

1. Simple Hysterical Dissociation

This group, in which the symptoms arise without any conscious motive and without other signs of psychiatric disorder, includes both (*a*) those cases in which there is little or no lapse of time or period of meditation after the precipitating physical or mental trauma, and (*b*) those which follow a long period of stress or conflict.

(*a*) As an example of the former one may cite the instantaneous paralysis of a limb which sometimes accompanies a relatively slight flesh wound. In such cases, if the hysterical dissociation is uncomplicated by any other disorder and psychiatric treatment is given early, the prognosis for return to duty should be good. Acute cases of this type, however, are rarely seen in our unit, which is analogous to a military base hospital. Where the removal of the hysterical symptoms releases much anxiety the prognosis depends upon the intensity of the objective signs of anxiety (see "5. Hysterical Complications").

(*b*) The following is an example of the latter type of reaction.

Case 1.—A stoker who joined the Navy two years ago was admitted following a hysterical fugue. He had an amnesia for the whole period since he joined the Service, but he showed no anxiety or other psychiatric disorder. In the course of investigation and treatment it materialized that he had joined the Navy primarily because a girl to whom he was attached admired the uniform. Shortly afterwards this girl gave him up and he became attached to another girl of a rather higher social standing. He had for long been preoccupied with the idea that he would never earn enough money in the Navy to justify his proposing marriage to this girl. This conflict gave rise to hysterical dissociation only after many months. The Service prognosis of such cases must be more guarded because the psychopathical mechanisms which produce the symptoms have often been operative long enough to impair the stability and adaptability of the personality. In other words, the longer a conflict persists before it is "resolved" by a flight into hysterical dissociation the more difficult it will probably be to get the patient to face up to the less pleasant alternative.

2. Hysterical Prolongation

Here the symptoms arise on a basis of previous organic or psychological disorder in association with a greater or less degree of consciousness of motive. Typical instances are the hysterical persistence of headache in patients convalescent from head injury and of tremor following acute

anxiety: the cerebral and emotional disturbances respectively are over, but the patient is reluctant to give up symptoms which are preventing his being ordered to face the same dangers again. In other cases, as those in which hysterical headaches or dyspepsia, for example, supervene upon a recovering affective reaction, the symptoms bring about a continuation of the illness by replacement or substitution rather than by direct prolongation.

Case 2.—A reservist aged 38 was drafted on recall to a destroyer, which was mined three months after his joining her. Following the immersion he developed a suppurative mastoiditis, which was operated upon successfully, with a good preservation of hearing. For several months afterwards, however, he complained of vague paraesthesiae behind the ear and numbness and weakness of the whole of the same side of the body. The continuance of these symptoms was dependent upon his reluctance to return to sea, and as there was considered to be no risk of the development of more serious psychiatric disorder he was given an explanation, was reassured, and was sent back for a preliminary period of shore service.

3. Hysterical Exaggeration

This takes the form of an exaggeration of an organic or psychological disorder which still exists.

Case 3.—A seaman cook aged 25 was drafted on conscription to a trawler; he had previously been a cook in the Merchant Service in large liners. He disliked the small ship and suffered a good deal from sea-sickness. The symptoms of sea-sickness became elaborated into a syndrome highly suggestive of duodenal ulcer, and they persisted when he came into hospital. Investigations for an organic lesion were negative, and it appeared that the elaboration had been possible because his father had for years been under treatment for duodenal ulcer and the symptomatology was table-talk at home. While he was in hospital retention of urine occurred, undoubtedly the product of hysterical simulation. But little anxiety accompanied this reaction, the symptoms subsided with explanation, and he was ordered to return to duty. In order, so far as possible, to prevent a relapse a recommendation was made for drafting to a larger ship.

Cases 2 and 3 show how hysterical prolongation and exaggeration can coexist. The symptoms in such cases are at least partially under conscious control, and to this extent will respond to alterations in incentive, to concessions, discipline, and deprivations. Here, again, if treatment is not too long delayed return to duty is often possible.

4. Hysterical Simulation

The "patient" classified under this category wishes to convince others that he is ill without himself really believing it. In the majority of cases the distinction between hysteria and malingering can be made fairly easily; but there is a borderland where endless discussion is possible over the degree of "conscious escapism" present, or whether a certain patient's loss of memory is "really genuine," or whether another patient can't hear or won't hear or can't hear because he won't. The practical issue, in the Services, is to distinguish as quickly as possible those who will make a satisfactory adjustment to Service demands and discipline after, on the one hand, a reasonable period of treatment or, on the other, disciplinary measures, from those who, even after the appropriate procedure has been carried out, will not make the adjustment. Kretschmer (1917), in a study based on German military psychiatric cases of the last war, deprecated attempts at a sharp aetiological distinction between hysteria and simulation, preferring to regard them as alternative paths open to persons of hysterical disposition. He stressed the importance of estimating separately in each case (1) the significance of the hysterical symptoms in the setting in which they occur—that is, in relation to any underlying disorder, and (2) the "health-conscience" (Gesundheitswille), or attitude of the patient towards illness, his readiness or unwillingness to succumb to minor ailments and discomforts.

Discipline is specific for malingering, and rapid diagnosis and prompt treatment provide effective prophylaxis. Malingering is rare in the Navy as a whole, and when it does occur ships' doctors are quick to recognize it and thereby prevent needless and harmful stay in hospital. Hence this diagnosis has been almost unknown during the first eighteen months of work in the neuro-psychiatric unit of our naval hospital. In civilian practice opportunities to apply discipline are limited: an explanation to relatives and injunctions to substitute firmness for sympathy, together with instructions to the patient to remain at work, are all that is usually possible. In the Services we are fortunate in having disciplinary measures available, comprising simple return to duty, return to duty with restriction of privileges, or actual punishment. One or other of these possibilities often provides the best treatment for certain cases of hysteria. To apply them in the wrong place or at the wrong time, however, will cause much suffering and may lead to serious mental breakdown. Like many of the most effective remedies of general medicine and surgery, discipline applied without proper discretion may be extremely harmful and, as when it precipitates suicide, actually lethal. The following is an illustrative case.

Case 4. Chronic Pathological Anxiety.—An able seaman aged 25 was admitted complaining of loss of self-confidence and inability to do his work. He joined the Navy in 1934 for seven years' service; three years ago he married, and since then he had been very keen to return to civilian life as soon as possible. During this war, which put an end to his hope of retiring in 1941, he had been engaged in submarine detection with convoys. In July, 1940, he left his ship without leave and made his way to his home town. He could not explain his unexpected arrival, so his brother fetched a doctor, and he was taken to a civilian hospital, where the diagnosis of a hysterical fugue was made. The presence of a very strong incentive was obvious, and the alternative diagnosis of desertion had to be most seriously considered when he was transferred to this hospital. Psychiatric examination, however, revealed a long-standing condition of pathological anxiety that began before he joined the Navy and was aggravated by the strain of duties for which he was barely intelligent enough and was temperamentally unsuited, and by the unresolved conflict between his desire to return to civilian life and his obligation to continue in the Service. The "genuineness" of his fugue was an issue of no practical importance, since on admission to hospital the anxiety and depression resulting from these constitutional weaknesses and topical conflicts had taken such a hold on him that invaliding was necessary, and even this, with its promise of release, caused no real improvement. In this man the escapist motive had been in the forefront of consciousness for a considerable time, but it was not effective until a fairly long struggle between his personal wish and ethical demands had seriously impaired his none too robust mental health.

5. Hysterical "Complications" of an Underlying Disorder

These conditions differ from Categories 2 and 3 in that the underlying disorder does not determine the form of the hysterical symptoms. The latter represent a secondary reaction produced by the operation of increased or prolonged stress upon an already impaired or a congenitally inadequate mental or physical constitution.

Case 5. Mental Backwardness with Hysterical Paralyses.—An able seaman aged 44, recalled after twelve years of civilian life, was admitted complaining of his left leg repeatedly "giving way without warning" during the last few months. No organic disease was found in the nervous system, and the only physical abnormality was an achlorhydric dyspepsia. His recurrent paralyses were undoubtedly hysterical, but recall

had rescued him and his family from a long period of insecurity due to irregular employment; he had been glad to go back and was not an "escapist." About three years ago, during a period of great domestic difficulty, similar symptoms had developed. He proved to be mentally backward: he had only reached Standard II at school at the age of 14, and his mental age by the Kent emergency test (modified for English use) was 9 years. He had been able to carry out routine duties in peacetime, but the conditions of service in a destroyer in wartime, with the long hours and responsibilities of watch-keeping, brought him up against his intellectual inadequacy. He became anxious and depressed, and his hysterical disability relieved an intolerable situation. He was wholly unaware of the origin of his symptoms. The most that could be expected of him in modern warfare was a simple job ashore.

Case 6. Endogenous Depression with Hysterical Fugue.—A conscript recruit 25 years of age, this patient in civilian life was a milk roundsman, and on two occasions in the past five years his barrow had been found abandoned in the street and he himself had been brought home by the police after wandering many miles into the country. Each of these incidents had preceded a depressive illness lasting about three months, during which he had been unable to work. There seemed to be no adequate psychogenic cause for these attacks, and both previously and in the intervening period he had been a satisfactory worker. The occasion of his admission to hospital in June, 1940, was his arrest by the military police when wandering without leave in a prohibited area many miles from his depot. A charge of desertion was made, but he was referred for psychiatric investigation. On admission he was depressed and retarded; his depression gradually lifted, and after two months in hospital he was bright and active. His normal personality was not hysterical, and the illness followed a course precisely similar to the description he gave of the two previous attacks. On the evidence the basic condition was considered to be a liability to recurrent attacks of endogenous depression, and, although he had completely recovered, he was invalided on account of the risk of a further breakdown. The wandering which heralded his depressive attacks was associated with amnesia, and it appeared to be a genuine instance of dissociation: on the first and second occasions, at any rate, there was no question of a conscious motive, and on the third it was unlikely that there was one. It is probable that an early stage of depression and retardation shortly preceded each of the dissociative episodes.

In neither of these cases, nor in Case 4, could a resort to discipline have had any result but to aggravate and prolong the illness, with a risk, at least in Cases 4 and 6, of precipitating a suicidal depression. Among the hysterical "complications" of depressive and anxiety reactions fugues have been fairly common. In a number of these cases in which a charge of desertion has been made the question has been answered in favour of the patient as the result of finding other objective signs of psychiatric disorder of a graver kind. To this group also belong most of the cases of pseudo-dementia and the few cases of Ganser syndrome that we have seen in this unit. In some instances a poor school record and an account from messmates and superiors of a genuine difficulty in learning and carrying out duties may indicate the presence of mental backwardness. In others one or more of the physical concomitants—loss of weight, fine tremor, raised pulse rate, raised systolic blood pressure, or dilated pupils—together with insomnia or recurrent dreams, may point to pathological anxiety. In others, again, some loss of interest or slowing up of thought and action, reduced self-confidence, irritability, constipation, and loss of appetite may reveal an underlying depression, recognition of which will set the more superficial and more striking hysterical symptoms in correct perspective. Hysterical symptoms have also occasionally been met with engrafted upon cerebral arteriosclerosis, cerebral syphilis, alcoholism, and schizophrenia. Indeed, patients who show a complete absence of hysterical features are rare in wartime psychiatry. The exceptions are striking. Occasionally men are admitted, having been sent sick against their will when observed to be severely disabled by anxiety or depressive reactions, who in the presence of the most intense objective symptoms and with excellent insight retain an unshaken morale. In many of these men the will to return to duty is weakened by the long period in hospital which their treatment inevitably demands; others are completely resistant to the hysterical utilization of their symptoms, and throughout their illness are ready to fulfil without hesitation any demands that might be made of them.

Of those patients in whom the hysterical manifestations are of secondary importance and who become fit to return to duty, as well as of those showing hysterical prolongation or exaggeration, many need certain concessions—e.g., a recommendation for drafting to a larger ship, a period of shore service, or a change of work—if they are to continue as useful members of the Service. Their value to the Service has to be balanced against the inconvenience and the danger of creating a precedent involved by the concession demanded.

Two further criteria—the family history and home atmosphere and the personality and past record—have been found helpful in assessing the likelihood of a satisfactory adjustment to Service demands.

Family History and Home Atmosphere

First, an inquiry is made into mental or nervous illness suffered by any close blood relation, and any marked personality characteristics. The occurrence of depressive, schizophrenic, or "neurasthenic" illness, for example, in such relations will prompt a search for signs of a more serious underlying disorder in the hysterical patient. Secondly, a picture is obtained of the economic standards and "work-conscience" of the family as a whole, and the patient's attitude and relation to these standards are ascertained. Is there a tradition of steady work and social reliability in the family? Is the patient above or below the average level of his parents and siblings in these respects? Is he temperamentally similar to the other members of his family, or in some way different from them—more dependent, for example? What was his school career in comparison with those of his brothers and sisters?

The facts thus elicited are of value in diagnosis in that they may lead to the assessing of the hysterical symptoms as a complication of some more fundamental instability based on inherited or early environmental factors. They also help in prognosis: the prognostic significance of a depressive psychosis of known duration in a brother or sister or of chronic invalidism in the father following "shell-shock" or "D.A.H." in the last war need not be emphasized, although it calls for careful evaluation. Both the inherited constitution and the patient's reaction to the level of "health conscience" prevailing in his family must be taken into account.

The Personality and Past Record

It is useful to make a distinction between hysterical symptoms arising in a setting of psychopathy and those which, as in the cases so far described, either complicate some other form of psychiatric disorder or are more or less isolated occurrences in a fairly stable personality. Here, as in Category 4, while the presenting symptoms may be produced by simple dissociation, prolongation, exaggeration, or simulation, the main prognostic criterion is the intensity of the underlying disorder—in this case of psychopathy. Of the multitude of traits and characteristics which have been described as part of the hysterical personality two at least have been too commonly met with for mention of them to be omitted in the consideration of

these cases: (*a*) a defective "health conscience," and (*b*) a desire to be the centre of attention and to obtain more appreciation from the community than is earned by actual social and personal value. A past history of neurotic traits in childhood and difficulties in adjusting to school life, as well as an unsatisfactory work record with many changes of job and much time off for minor ailments, is commonly found among hysterical psychopaths. A large number of those who broke down had never, on account of ill-health, inefficiency, or distaste, held a job for long in civilian life.

Case 7.—A Newfoundlander enlisted with most of the eligible men in his village in January, 1940. His application was a half-hearted gesture which both he and his mother and, as he said, the whole village were astonished and dismayed to find successful. He had been known for years as a semi-invalid, taking after his father, who had twice been a patient in a mental hospital. He had given up one job after another because it was too strenuous, and his work record consisted of short periods in labouring and farming jobs, long-shore fishing, and fish-packing, interspersed by considerable intervals for rest and recuperation. On arrival in this country his humble position, the disappointing pay, and the lack of interest in his hypochondriacal complaints shown by his messmates and superiors in the training depot provoked an intense resentment against the authorities who passed him as physically fit to join up. After a few weeks he reported at the sick bay complaining of pain in the back, which he alleged had been brought on by rifle drill, and frequency of micturition. Full urinary investigation was carried out, including even an intravenous pyelogram and a radiograph of the spine and renal areas: no physical abnormality whatever was discovered. On admission to the Royal Naval Auxiliary Hospital his mental state can be briefly described as disgruntled petulance. He was completely taken up with his own symptoms and disappointments; he showed no interest in the war news or the other patients, worked mechanically in the occupational department, and went through the movements in the physical-training class in feeble apathy. He made no improvement at all until the decision to invalid and repatriate him was made.

Case 8.—An ordinary seaman aged 25 volunteered after a minor quarrel with his wife in April, 1940. In July he got his first draft, to a small submarine-chaser. For the whole of the two months he was with her she was in harbour fitting out, and only twice went to sea on trials. He was terrified by heavy air raids on the harbour, and one night, returning from leave, he collapsed in the street and was taken to hospital by the police. Shortly afterwards he was given sick leave: he went home, and overstayed his leave because he "could not face it again." He could not explain to his relatives his remaining at home, so he spent three days wandering round the city without food and then reported at the local naval depot. He was sent from there to our hospital. He looked and played the part of a hopeless and beaten man; his voice was rather ungenuinely tremulous and tears were "not far away." He said he would rather go to gaol than return to duty and that he had been foolish not to plead conscientious objection. He showed none of the physical signs of anxiety, and slept well without drugs. He made no complaint of illness: "Just funk, I suppose; it's a rotten way to be, but whenever I think of going back my stomach turns over and over." He was of average intelligence and his work record in civil life had been fairly good, although he had always looked for jobs near his home, as he was very dependent upon the sympathy of his family. His personality was immature and egocentric, and his freedom from "symptoms" appeared to spring from a complete absence of struggle against his fears. He showed no sense of social responsibility and spent much of his time in hospital spreading discontent and resentment among the patients. In such a case as this the role of the doctor can only be to report his findings and to advise the executive authorities, with whom the final decision as to disposal must lie.

Case 7 is an example of defective "health conscience"; Case 8, of defective morale. A description of the latter case is given although it cannot be classified as hysterical, because here, as with the typical hysterical psychopath, failure in the Service was an expression of the inadequacy of the total personality. Both cases illustrate a very serious problem of disposal. No medical treatment is of any use, and if these men were sent back to duty further psychopathic developments would be certain to occur and the lives of others might be endangered. Discharged to civilian life, they are a living invitation to seek escape through "neurosis" and a burden on the community. No satisfactory disposal is available: rejection at the recruiting station, or as early as possible during training, and direct drafting to a labour camp or rehabilitation centre, where suitable manual work is done under modified Service discipline, is urgently called for. Such centres would be valuable for many types of case besides those described here. Cases of deficient morale are uncommon, but the hysterical psychopath has often been met with among new recruits. Work and discipline are the best treatment for both, and when similar cases in the other Services are taken into account the problem is already large enough to justify prompt action. The enlistment, training, and hospital treatment of such men are an extravagance which, if it could be afforded in the past, must eventually be terminated by increasing financial stringency and demands for labour.

Summary

A brief description is given of some hysterical reactions and one case of defective morale which have been seen in the naval psychiatric service. An attempt is made to classify such reactions by means of an assessment of the symptoms in the setting in which they occur. This has been found to facilitate prognosis and appropriate disposal. The more general question is raised of the most useful and economical disposal of the psychopath in wartime.

THE STABILITY OF TETANUS ANTITOXIN UNDER SUBOPTIMAL STORAGE CONDITIONS

BY

C. RUSSELL AMIES, M.D., D.T.M.&H.

(From the Serum Department, Lister Institute, Elstree)

Under normal conditions it is the usual practice to store sera and other immunological products at a temperature slightly above 0° C. At present, however, stocks of tetanus antitoxin and other sera have to be maintained at civilian first-aid posts and dispensaries where refrigerators are not available. Moreover, under war conditions it is not always possible to obtain cold-storage on ships carrying supplies of serum over-seas. It is therefore a matter of importance to know the rate at which antisera deteriorate under suboptimal storage conditions. Some information on this subject is already available, but the results obtained by earlier workers were derived from the study of sera of low titre, and it cannot be assumed that these apply to sera of high potency obtained by improved methods of immunization. It may therefore serve a useful purpose to record the results of some recent investigations of this problem.

The effect of temperature has been studied more completely on diphtheria antitoxin than on other antisera. Anderson (1910) and MacConkey (1913, 1917) reported that diphtheria antitoxin lost about 6% of its activity after being stored for a year in the refrigerator and about 10% per annum at 15° C. MacConkey (1913) also found that this antitoxin when stored at 36° C. lost half of its activity

in a year; while Glenny (1913) reported that antitoxin stored at 37° C. for four and a half years had lost 82% of its activity, and over 90% after seven years. Results with tetanus antitoxin concentrated by the Banzhaf-Gibson method, still employed in a modified form in some serum laboratories, indicate that this antitoxin has a similar heat-inactivation rate.

The material for the present study consisted of samples of unconcentrated antitoxin from individual horses or from large pools representing several bleedings from a group of twelve to twenty animals. All the samples contained 0.35% of cresol as a preservative. Some were kept in the laboratory under known conditions of temperature, while others were samples returned from first-aid posts and dispensaries. The conditions to which these latter had been subjected were not precisely known, but it was considered that the analysis of such random samples should give a fair indication of the effect of storage under the actual conditions of distribution. All the assays were carried out on guinea-pigs at the L+/5 level, the same test-toxin being used throughout.

Control Series: Storage in the Cold, at Room Temperature, and at 37° C.

Two horses, "Equa" and "Calidus," received the same course of immunization with tetanus toxoid and alum. Samples of the serum from each horse were stored (in rubber-capped 50-ml. bottles) in the cold room at 2° to 4° C., in a glass-fronted cupboard in one of the laboratories where the seasonal variation in temperature is between 10° and 25° C., and in an incubator maintained at 37° C. The samples remained under these conditions for one year, the potency of each being tested at frequent intervals during this period. For the sake of brevity, however, only the initial and final titres are given.

Potency of Serum in International Units

	Serum "Equa" stored at			Serum "Calidus" stored at		
	2°–4° C.	Room Temperature	37° C.	2°–4° C.	Room Temperature	37° C.
At start of experiment	8,000	8,000	8,000	1,350	1,350	1,350
After 1 year	8,000	7,250	4,200	1,300	1,250	750
Loss	Nil	9%	47%	4%	7%	44%

Tests on Returned Samples

A batch of unconcentrated tetanus antitoxin designated No. 423 was issued to various centres acting as medical stores for the A.R.P. services. From time to time bottles of this antitoxin were returned, and these were tested to determine the fall in potency which had occurred. Samples of this same batch of antitoxin were kept in the laboratory at room temperature (10° to 25° C.) and in the cold room, and these were also tested at intervals. The results may be summarized as follows:

			Percentage Loss
1	Batch No. 423, original test	1,300 I.U./ml	—
2	Retested after 2 years at 2–4° C.	1,200 "	8
3	Retested after 2 years at room temperature	950 "	27
4	Samples returned after 2 years:		
	9 samples from different centres	1,200 "	8
	4 " " "	1,100 "	15
	2 " " "	1,000 "	23

The greater loss found in the sample that was maintained in the laboratory at room temperature was probably due to the fact that the room was furnished with skylights and consequently became very warm during the summer.

The Effect of Freezing

It is commonly believed that the freezing of an antiserum results in a considerable fall in antibody titre. This is said to arise from the denaturation of the antibody globulin by the phenol or cresol preservative, the effective concentration of which is considerably increased when the water separates out in the form of ice. Glenny, Pope, Waddington, and Wallace (1925) have shown that this phenomenon is responsible for the increased toxicity observed in toxin-antitoxin mixtures used for diphtheria prophylaxis. This, however, must be regarded as a special case, because carefully controlled experiments with a number of different antitoxins and anti-bacterial sera have failed to show any appreciable diminution of potency as the result of repeated freezing and thawing. Sealed glass ampoules very rarely break when their contents become frozen, since the air space in the neck of the ampoule allows the fluid to expand before it freezes. The rubber caps employed to seal multiple-dose containers may, however, be forced off if insufficient air space is provided. If these mechanical risks are avoided the contents of a bottle or ampoule which has been frozen may be used with full confidence that no appreciable deterioration of the antibody has occurred.

Conclusion

Tetanus antitoxin in the form of natural horse serum loses less than 10% of its potency per annum when kept at room temperature under reasonably good conditions. Samples maintained at 37° C. for a year lost less than 50% of their activity. These results are in agreement with those obtained by other investigators. The freezing of serum containing 0.35% cresol has no appreciable effect upon the antibody.

Clinical Memoranda

Peripheral Neuritis and Acute Rheumatism

The interest of the following case lies in the rarity of polyneuritis as a complication of acute rheumatism.

CASE HISTORY

A pale stout boy aged 10 was admitted to the rheumatism unit of Queen Mary's Hospital, Carshalton, on August 3, 1939. His former history was that he had been operated on at the end of May, 1939, for acute appendicitis. Shortly afterwards he complained of pain in one wrist. Joint pains spread and persisted, and he was transferred to Carshalton. There was no previous history of rheumatism.

On admission the child looked ill. The skin was unusually dry, and he had a malar flush. He was apyrexial; no signs of chorea and no rheumatic nodules were present. There was a collapsing pulse and clear evidence of mitral and aortic incompetence. It is of interest to note that no evidence of aortic disease was observed on July 20. During the next few days he became dyspnoeic, was very difficult with his food, and vomited occasionally. There was no cyanosis or oedema of the legs. On October 16 he began to be incontinent of faeces. Control was regained about a week later. On October 26 bilateral drop-foot was noted. All the muscles below the knees were wasted, and the tendon and plantar reflexes were absent. There was diminished sensibility below the knees, and the muscles were tender on pressure. At this time the boy became very awkward in the use of his hands. This suggested chorea, but marked muscular wasting was observed here also. The cerebrospinal fluid was examined on two occasions and was not abnormal.

The patient was treated with vitamin B_1 in the form of betaxan; 450 mg. was given over a period of seven weeks, and during that time he also received bemax. Salicylates

were given in moderate dosage, but not continuously. There was no noticeable improvement in the neuritis, and the general condition steadily deteriorated. On February 26, 1940, oedema of the legs and considerable hepatic enlargement were seen. The patient died on March 3.

Discussion

In chorea mollis there is not the same degree of wasting and there is choreiform movement at some stage. The only symptom in our case suggesting chorea was the clumsiness of the fingers. This was attributed to the obvious muscular atrophy. The absence of knee- and ankle-jerks is again the opposite of what is usually found in chorea. There was no palatal palsy to suggest a diphtheritic lesion, and no family history of ataxia.

Gordinier (1891) described a case of acute rheumatism in a man, aged 31, of temperate habits. The onset was with typical pain and swelling of both ankles and one elbow and shoulder. Three months later there developed weakness and wasting of all four limbs, bilateral drop-foot and wrist-drop, and signs of mitral stenosis. Hypo-algesia over the inner aspect of the forearm and outer sides of the ankles was also present. The knee-jerks were absent. Signs of pericarditis developed before death after an illness lasting four months altogether. The post-mortem examination showed a fibrinous pericarditis, mitral stenosis, and aortic stenosis. The ulnar, musculo-spiral, and anterior crural nerve trunks appeared swollen and congested. There was microscopical evidence of parenchymatous degeneration and interstitial neuritis. No changes were seen in the anterior horn cells of the cord. Pierret (1912) reported the case of a man aged 29 who during convalescence from two separate attacks of acute rheumatism developed brachial neuritis with pain and paralysis of the left deltoid and extensors of the wrist. Reinhold (1926) described an attack of acute rheumatism in a man aged 21 who developed a total left facial palsy. Morquio (1930) reported the case of a child aged 12 whose main rheumatic symptom was torticollis. She developed signs of a mitral affection and, six weeks from the onset, a complete paralysis of the right hypoglossal nerve. There was a permanent hemiatrophy of the tongue.

In the adult it is important to exclude an alcoholic or other toxic aetiology. Bouchut, Froment, and Badinand (1936) described the case of a woman aged 44, "paraissant pas entachée d'éthylisme," who presented signs of mitral incompetence together with absent tendon reflexes in arms and legs, awkwardness of the fingers, and aphonia from left recurrent paralysis. The aphonia persisted for two months and the reflexes were absent for two years, during which she was severely ill with pericarditis and effusion, pleural effusion, and auricular fibrillation. She ultimately recovered.

Gounelle and Warter (1937) reported the case of a youth of 18 who developed paralysis of the anterior leg muscles during a severe attack of acute rheumatism. The knee-jerks were unaffected, but the ankle-jerks and plantars were absent. Incontinence of urine occurred in the seventh week. The cardiac lesion was aortic incompetence with pericarditis. He was given 150 grains of salicylate daily for eight weeks and physiotherapy in the form of hot baths, hot-air baths, and galvanism during convalescence. The paralysis was completely cured in eight months.

From this short series of cases it would seem that peripheral neuritis or polyneuritis may occur in the course of the more severe attacks of acute rheumatism. This complication does not seem to influence the ultimate prognosis. In my case treatment with the antineuritic vitamin was without noticeable effect. Perhaps better results might be obtained from the higher dosage of salicylates employed on the Continent.

I have to thank the Chief Medical Officer, London County Council, for permission to publish this case.

JOAH BATES, M.B., B.S., D.C.H., D.P.M.,
Late Assistant Medical Officer, Queen Mary's Hospital, Carshalton.

Reviews

HUMAN PARASITOLOGY

The Parasites of Man in Temperate Climates. By Thomas W. M. Cameron, M.A., D.Sc., Ph.D., M.R.C.V.S. (Pp. 182.) Toronto: University of Toronto Press. 1940.

The author of this short textbook is professor of parasitology in McGill University, and the work is based on the lectures on animal parasitology given there to the students in the medical school. Detailed accounts are given of those parasites which occur in North America and Great Britain, and brief accounts of others which may from time to time be introduced from the Tropics. The book is intended, therefore, for the medical man who practises in the English-speaking temperate and subtropical zones. In his preface the author points out that so far parasitology as a subject commensurate with bacteriology has been taught only in schools of tropical medicine. Parasites, however, are not confined to the Tropics; moreover, owing to more rapid and frequent communication between temperate and tropical countries it is increasingly important for medical men to have some knowledge of diseases which occur outside their immediate environment.

The parasites described belong to the protozoa, helminths, leeches, and arthropods. The intestinal protozoa are dealt with in a clear but concise manner. The subject of malaria is fully described and includes a summary of the chemotherapy of the disease as given in the report of the Malaria Commission of the League of Nations. The section on helminths is the largest and possibly the most useful in the book. A description is given of modern methods for the diagnosis of *Enterobius vermicularis* infestation. A very full account is given of *Trichinella spiralis*, an important parasite in many temperate climates; thus, it is stated, a recent survey shows an infestation rate of 17% among the inhabitants of the U.S.A. The morphology and life-history of the worm, the diagnosis and symptoms, and the methods of prevention of the disease are all very completely described. The author considers that rats are not an important source of infection to pigs, but that uncooked garbage containing scraps of infected pork is the main source of infection in these animals. Man is infected most usually by eating undercooked pork.

The hookworms and the disease caused by them are also very fully dealt with. In the description of *Strongyloides stercoralis* no mention is made of the discovery by Kreis and Faust of the parasitic male worm. The section on arthropods is practical and concise, and contains, in addition to numerous line drawings, some very beautiful half-tone illustrations.

The book is well produced, being printed on excellent paper, and gives a clear account of the limited number of parasites most commonly met with in temperate zones.

BLOOD COAGULATION IN HEALTH AND DISEASE

Hemorrhagic Diseases. Photo-Electric Study of Blood Coagulability. By Kaare K. Nygaard, M.D. (Pp. 320; illustrated. 28s. net.) London: Henry Kimpton. 1941.

This work is not a textbook on the haemorrhagic diseases but, as its subtitle indicates, a highly technical study of the coagulation of the blood in health and disease. Having cleared away any possibility of misunderstanding of its purpose, we should like to go on at once to say that it is an extremely valuable addition to the literature of haematology. Dr. Nygaard has himself been engaged in investiga-

tions on blood coagulation for the last ten years, and in addition he has reviewed the literature. His book has been completed at a fortunate moment, for we appear to be on the eve of considerable advances in knowledge of the haemorrhagic diseases, as witness recent work on prothrombin, vitamins C, K, and P, and the action of snake venom. Coagulation is normally a potential quality of the blood, which is manifested only *in vitro*. It therefore depends not only on intrinsic haematological factors but on external non-haematological factors. From the technical point of view much depends on the simplification and standardization of these extrinsic factors, and most haematologists who have worked in this field will agree with Dr. Nygaard that blood coagulation is best studied by means of recalcification of the citrated or oxalated plasma.

Methods of studying coagulation can be roughly divided into those which depend on alterations in viscosity and optical methods. When plasma coagulates it becomes more opaque, and Dr. Nygaard has devised a photo-electric method by which it is possible to make a permanent record or *coagelgram* with time markings of this process. With this technique coagulation can be divided into four phases: the period of dissociation or latent period, the period of fibrin formation, the rest period, and the period of clot retraction. The method can easily be adapted to the estimation of accelerated clotting or prothrombin times. After discussing the various conditions which modify coagulation *in vitro*, Dr. Nygaard goes on to show that coagulation is prolonged in haemophilia, thrombocytopenic purpura, and prothrombin deficiency; the last being most commonly found in jaundice and melaena neonatorum. The evidence suggests that in both haemophilia and thrombocytopenic purpura the fault is due to deficiency in the thromboplastin or tissue extract factor.

The writing is lucid, and the author has a disarming modesty, but we believe he is justified in his hope of having made a constructive contribution to his subject.

BROMPTON REPORTS

Brompton Hospital Reports. A Collection of Papers recently published from the Hospital. Volume IX, 1940. Published by the Research Department of the Hospital. Copies can be had from the Secretary, the Hospital for Consumption, Brompton, London, S.W.3, price 5s. 7d., post free.

A further batch of papers recently published by members of the staff of the Brompton Hospital have been collected in Volume IX of the *Brompton Hospital Reports*. Of topical interest are two papers on war injuries of the chest and on the late effects of penetrating wounds of the chest by J. E. H. Roberts and C. Price Thomas respectively. In another article Mr. Roberts discusses primary carcinoma of the lung; he stresses the importance of recognizing and investigating the early symptoms of this by no means rare disease (230 cases reached the Brompton and St. Bartholomew's Hospitals in 1938) if surgical therapy is to prove of avail. In a paper entitled "The Diagnosis of Pulmonary Tuberculosis without Bacteriological Confirmation: Clinical Aspects," J. G. Scadding in effect ably discusses the differential diagnosis of pulmonary tuberculosis with emphasis on the atypical forms of pneumonia, to the study of which he has given detailed attention. Various aspects of tuberculosis form the subjects of most of the remaining papers: contact infection in childhood, prevention of pulmonary tuberculosis, its treatment by phrenic paralysis, the termination of artificial pneumothorax, the relation between pulmonary tuberculosis and pregnancy, and tuberculous tracheo-bronchitis. A long article on the relation between chronic iridocyclitis and tuberculosis, by W. D. W. Brooks, F. A. Juler, and E. R. Williams, will stimulate interest in the subject; but the evidence presented cannot be considered sufficient to establish tuberculosis as the cause of the condition unless we assume that the tubercle bacillus or some form of this organism is capable of producing tissue reactions different from those usually found. An illustrated article on diseases of the middle lobe of the right lung and interesting case reports complete the contents of the volume. The usual statistical tables summarizing the work of the hospital have been omitted this time, no doubt because of the extent the war has interfered with that work.

FEAR AND FAITH

Fears may be Liars. By John A. Ryle, M.D. (Pp. 95. 3s. 6d. net.) London: George Allen and Unwin, Ltd. 1941.

That fear is defensive and pain protective in origin may well be recognized in medical circles, but it is good, particularly at the present moment, that the implications from this dictum should be elaborated in language suited to the general reader. Taking his title from Clough, Professor Ryle has done this in *Fears may be Liars*, and comes to conclusions that might be summarized in Sir Philip Sidney's words, "Fear is more pain than is the pain it fears." The Elizabethans feared death as the end of an exciting adventure, the Victorians compensated for that fear by absorbing interest in personal immortality; here is a creed expressed in terms which will comfort and reassure those to whom the dogmas and consolations of orthodox religion have ceased to carry conviction, combined with medical evidence that deprives the moment of death of much of its sting. To this is added a robust faith in the value of life, and a zest for living not merely as an individual but as a member of a community that will persist. That fear may be best resolved by effective and collective action is a lesson we are all learning to-day. When Sir Edward Grey said in 1914 "the lights in Europe are going out one by one" he was more prophetic than he knew, and this book has been written, in the author's own words, "for ordinary men and women who, in this their finest hour, yet find themselves groping in the black-out of the mind for a match or a torch to guide them towards a friendly door." A tract for the times, sympathetically conceived and finely expressed.

Notes on Books

A second edition of *The Care of the Aged, the Dying, and the Dead*, by Dr. ALFRED WORCESTER, is published in this country by Baillière, Tindall and Cox. The text of this book is contained in seventy-four pages and about 15,000 words. The price charged for it is 8s., which, making allowance for transit across the Atlantic in wartime, is too high for most pockets. A single reading will be of value to many, and it is a pleasant exercise, for the American publishers have fulfilled their desire to present a volume which, as to type, paper, and binding, is appropriate and satisfactory, and the author's style is agreeable and easy. On its first appearance in 1935 the book was reviewed in this *Journal*. The fact of a second edition being published shows that it performs a useful service in directing attention to certain regions of medical practice which are neglected in most ordinary textbooks. It is intended mainly for the instruction of senior students and young practitioners in the art of practice rather than as any contribution to the science of medicine. The author's suggestion of the need for specialization in the field of practice dealt with can scarcely be approved; but if the reader is not offended by his initial statements that "the advance of medicine is now furthered only by specialists" and that in the particular fields of the general practitioner "neither medical science nor the art of practice advances," and if he will allow

NOW BRITISH PRODUCTS

THE SAFEST AND MOST SUCCESSFUL CONTRAST MEDIA FOR PYELOGRAPHY

PRODUCTS OF THE GLAXO LABORATORIES

PYELECTAN
Brand of IODOXYL INJECTION

For intravenous pyelography. Each 20 cc. ampoule contains in aqueous solution 15 gm. of the disodium salt of 3:5-di-iodo-4-pyridoxyl-N-methyl-2:6-di-carboxylic acid (Iodoxyl). Gives dense, defined shadows. Ampoules in boxes of 1 x 20 cc., 10,6; 5 x 20 cc., 52 6; 1 x 3 cc., 2/6.

PYELECTAN (Retrograde) For instrumental pyelography. Each 10 cc. ampoule contains in aqueous solution 2 gm. of the above compound, with 0·1 mg. of mercuric oxycyanide.

10 cc. ampoule, 3,6.

PYELOSIL
Brand of DIODONE INJECTION

For excretion pyelography and other radiological examinations. Each 20 cc. ampoule contains in aqueous solution 7 gm. of the di-ethanolamine salt of 3:5-di-iodo-4-pyridone-N-acetate (Diodone). For intravenous injection, or can be given subcutaneously when a suitable vein cannot be found. No sloughing follows if 'Pyelosil' escapes into the perivenous tissues. Ampoules in boxes of 1 x 20 cc., 10,6; 5 x 20 cc., 52 6; 1 x 3 cc., 2/6.

Special literature for all the above preparations is available on request. All prices are subject to usual professional discount.

GLAXO LABORATORIES LTD., GREENFORD, MIDDLESEX BYRon 3434

KAPILON BRAND

to normalise blood-clotting time

in neo-natal haemorrhage and obstructive jaundice

The tendency to haemorrhage in obstructive jaundice is due to the prolonged blood-clotting time which in turn is caused by a prothrombin level much below normal. Recent investigation makes it clear that a similar deficiency occurs in neo-natal haemorrhage. In the treatment of such conditions, Kapilon vitamin K analogues are specific. When rapid effects are essential, and when there is restricted power of fat-absorption (e.g. obstructive jaundice), Kapilon should be injected. The effects can be observed within 3-8 hours, the prothrombin level being raised from 10 or 20 per cent to as much as 100 per cent.

For neo-natal haemorrhage, when there is no interference with fat-absorption, many practitioners will prefer to give Kapilon orally. For prophylaxis, the tablets may be given to the mother, ante-partum. Kapilon liquid is most suitable for the infant, to be given either prophylactically or curatively. In neither case is it necessary to give bile salts.

PRODUCT OF THE GLAXO LABORATORIES

'KAPILON' AMPOULES
Each 1 cc. ampoule contains 5 mg. of 2-methyl-1,4-naphthoquinone, in vitamin alcoholized arachis oil. Boxes of 5 x 1 cc. ampoules, 7,6.

'KAPILON' TABLETS
Sugar-coated. Each contains 10 mg. of 2-methyl-1,4-naphthohydroquinone diacetate. Bottles of 25, 3/3; 100, 10/6.

'KAPILON' LIQUID
Each cc. contains 10 mg. of 2-methyl-1,4-naphthohydroquinone diacetate in arachis oil; 20 cc. phials (with 5 m. dropper) 3/-.

Prices subject to usual professional discount. The Ampoules are subject to purchase tax.

GLAXO LABORATORIES LTD GREENFORD MIDDLESEX BYRon 3434

'Elastoplast' for Head Injuries

A SHORT length of 3 in. 'Elastoplast' Bandage, tailed at each end to accommodate the ears, retains the dressing firmly in position without discomfort. This type of dressing is inexpensive and can be applied quickly. In scalp injuries it retains the pad in position where other bandages would become displaced during sleep.

Scalp injuries accompanied by concussion may also be conveniently dressed turban fashion with 'Elastoplast.' The patient is not irritated by pressure on the scalp, as the elasticity of the fabric ensures a firm dressing in spite of the patient's restlessness.

'ELASTOPLAST' BANDAGES AND PLASTERS ARE MADE BY T. J. SMITH & NEPHEW LTD., HULL

for a not infrequent exaggeration of statement, he will find in its three chapters some sound and helpful suggestions which increasing experience will enable him to profit by and to extend.

Messrs. A. and C. Black, Ltd., have issued a new series of little books entitled *Nature at Work*, by E. M. STEPHENSON, M.Sc., in which "Nature study is blended with a simple account of farming and gardening activities." They are intended to be read by junior pupils from 7 to 11 years of age, and constitute an admirable and attractive introduction to the subject. They are suitable for use in both urban and rural schools. Book III (2s.) has been sent to us for notice, and it seems excellent for its purpose and likely to attract and enhance the interest of junior scholars in Nature study. Its subjects and the order of their consideration are miscellaneous rather than systematic. They include the soil and the farm, the sea-shore and the fish shop, and, of course, both plants and animals. Illustrations are abundant and appropriate. Though there are only three books in this series there is a more substantial small volume entitled *Nature Study and Rural Science*, by the same author (3s.), issued as a teacher's book for a four-years course. This is excellently designed and should prove of very great value to the teacher in arranging and conducting such a scheme of work. It contains hints for preliminary lessons, a commentary on each book of the series amplifying the text and exercises and suggesting further practical work, together with a scheme for suitable field work.

A new edition of Dr. E. B. CLAYTON'S *Actinotherapy and Diathermy for the Student* has been published by Baillière, Tindall and Cox at 8s. 6d. It is a pleasant and practical outline for students of massage. Since the publication of the first edition, short-wave diathermy has been added to the syllabus of the C.S.M.M.G. examination, and the last chapter, dealing with this subject, has accordingly been rewritten. The book will prove of real value to those for whom it is intended, both in preparing for examination and in the earlier years of practice after qualification.

Preparations and Appliances

STRETCHER-SLING FOR USE IN CASUALTY EVACUATION TRAINS

Dr. M. HAWKE (train medical officer, Casualty Evacuation Train No. 9, Ministry of Health) writes:

Since the beginning of the war various methods have been suggested for suspending and reinforcing stretchers in casualty evacuation trains, and the accompanying diagrams illustrate a new type of stretcher sling which combines the merits of extreme simplicity and economy.

Each sling is made by splicing with four tucks a length of white sisal rope measuring approximately three yards, and

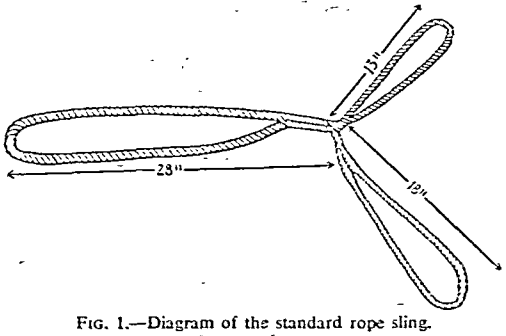

FIG. 1.—Diagram of the standard rope sling.

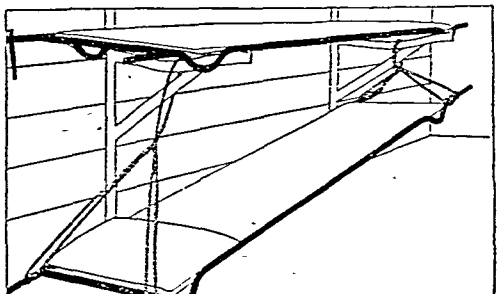

FIG. 2.—Foot of stretcher raised nine inches; head of stretcher raised three inches.

thereby producing three loops, as shown in Fig. 1 of the accompanying illustrations. A single strand of this rope will support over 18 cwt., and will stretch to the extent of only 5%. It will be observed that by varying the method of application, and also the number of turns of the loops in relation to the supporting stretcher handle, a patient can be supported, or suspended in the stretcher, in almost any desired position. These slings serve the important function of insulating the stretcher and its occupant from vibration when the train is in motion, and they also serve, with the assistance of rolled

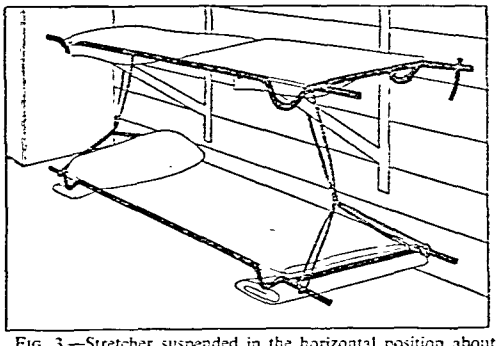

FIG. 3.—Stretcher suspended in the horizontal position about four inches from floor of coach. Swaying is prevented by placing a rolled blanket under each end of stretcher.

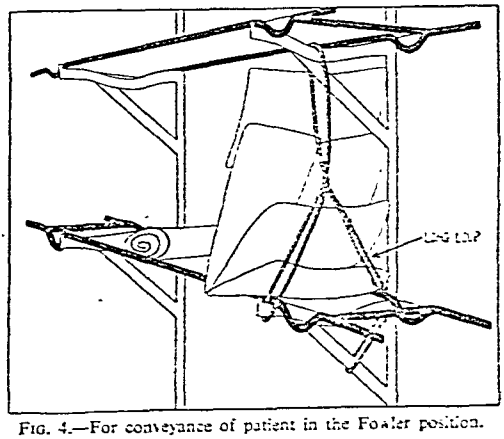

FIG. 4.—For conveyance of patient in the Fowler position.

blankets or pillows, as efficient but less cumbersome substitutes for bed-rests.

I gratefully acknowledge the courtesy of the Hospital Officer, Ministry of Health, Leeds, for permission to publish these notes, and would extend my appreciation to Messrs. British Ropes Ltd. for providing the necessary material for use throughout the train.

CRYSTALLINE ENZYMES

It is a commonplace nowadays that maintenance of the life of all living things depends upon physical and chemical processes which are made possible by a series of catalysts elaborated by the organisms themselves. From this point of view the living body as a whole may be called an autocatalytic machine. Whereas these catalytic agents deal primarily with the normal necessities of the organism, it is remarkable how readily they can be adapted to deal with substances administered for various purposes and normally foreign to it. Although it is inevitable that we should study the catalytic reactions in the body separately, no significant picture of them will be obtained until they can be fitted into the total scheme of the living unit. The construction of such an understandable scheme will be a laborious process. At present a number of aspects of the subject have been clarified. The complicated system of enzymes, about whose nature and action there has been so much controversy, are vital to the sequence of metabolic events in the organism. From the present standpoint all these arguments seem a waste of energy. Until recently all the experiments were performed with very crude preparations; thus, although there may have been much truth in what each disputant maintained from his experiments, no finality could be reached until preparation of the pure enzyme was made possible.

When, in 1926, Sumner isolated from soya bean a crystalline cell catalyst which appeared to be identical with urease, the enzyme which rapidly decomposes urea into ammonia and carbon dioxide, a new field of enzyme research opened. Pepsin was isolated and crystallized shortly afterwards, and in the succeeding years pepsinogen, trypsin, and other pancreatic enzymes; papain (kathepsin), amylase, lysozyme, and others were crystallized. Northrop,[1] who has been in the forefront of this work, states that, so far as is known now, these enzymes are simple proteins—that is, they do not embody groups other than amino acids. The enzymes are catalysts of hydrolytic processes; for example, trypsin acting on proteins with the characteristic linkages (-CO-NH-) splits them and adds the molecule of water thus: $(-CO-NH-)+H_2O\rightarrow(-COOH)+(-NH_2)$. Catalase, an enzyme which catalyses the reaction $2H_2O_2\rightarrow2H_2O+O_2$, and tyrosinase, which splits the amino acid tyrosine to form derivatives of catechol, have also been isolated and crystallized. They differ in structure from the hydrolytic enzymes in that they are conjugated proteins (haemoglobin is a conjugated protein—the protein globin + the prosthetic group haematin).

The significance of these isolations and crystallizations of enzymes depends upon whether it can be demonstrated unequivocally that the substances obtained are chemical individuals and possess the specific properties attributed to the enzyme. So long as the purity is in doubt it is open to critics to object that the active enzyme is adsorbed on the protein and responsible for the activity. The criteria for purity of an organic compound cannot be applied to these enzyme proteins, or indeed to any protein. Hence other criteria must be used (for example, solubility curves) which are not absolutely satisfied even by such well-studied proteins as haemoglobin and egg albumen. If the deviations from theoretical requirements are no greater than those observed for the purest specimens of the latter, then comparative purity can be inferred. In at least one case (chymo-trypsinogen) the correspondence to theoretical requirements is very close and indicates that this protein is one of the purest ever isolated. Other methods (sedimentation in the ultra-centrifuge; rate of migration in the electrophoresis cell) are also used to test for purity of proteins, but are perhaps not so reliable as the solubility test. These various methods do not always give results consistent one with the other: thus crystalline pepsin, which appears to be a chemical individual by the sedimentation and electrophoresis test, is shown to consist of two or more components by the solubility test. Clearly more work is necessary to establish once and for all that enzymes are definite chemical individuals, though it looks as if it is a mere matter of time before this is done.

The familiar fact that heat destroys the activity of enzymes and that they have an optimum range of reaction (*p*H) for their activity is demonstrable also with the crystalline preparations. The fact that the crystalline preparations can be inactivated by other proteolytic enzymes also points to a very close relation between the protein and the enzyme. These and other findings suggest strongly that the enzymatic activity is vested in the protein molecule itself, but it is, as Northrop states, impossible at present to say what chemical structure is first responsible. By introducing certain groups and elements—for example, acetyl groups and iodine—into the molecule, and by determining the effect on activity, it can be shown that the free amine groups are not necessary for the activity, but that the phenolic groups (for example, the -OH in tyrosine) are. A very interesting consequence of the crystallization of enzymes has been the clearer picture that can now be obtained of the puzzling phenomenon of the activation of pancreatic trypsinogen. The older experimenters showed that freshly secreted pancreatic juice is inactive and is activated by the so-called enterokinase present in extracts of the small intestine. This classical experiment, using other pancreatic juice or amorphous preparation of pancreas, is repeated by every class of chemical physiology. It has now been demonstrated that amorphous preparations contain traces of a substance (this has also been isolated in crystalline form) that inhibits trypsin. Crystalline trypsinogen, however, freed from such inhibitor, is activated in neutral solution by the most minute trace of trypsin, and autocatalysis proceeds uninterruptedly. In the case of *in vivo* activation of pancreatic juice by enterokinase, the old controversy whether this is an enzymatic reaction or whether active trypsin is a compound of trypsinogen and kinase (stoichiometric view)

[1] *Johns Hopk. Hosp. Bull.*, 1940, 66, 207.

seems at least in part to have been cleared up. By using purified materials Kunitz has found that confusion arose because an inert protein and the active trypsin are formed simultaneously. The relative amounts of the two depend upon the acidity of the reaction mixture. The active trypsin preponderates in slightly acid condition, while the inactive protein appears in greatly increased quantities in neutral or slightly alkaline conditions. The isolation and crystallization of pepsinogen were followed by the proof, confirmatory of the earlier work on crude preparations, that it has no proteolytic activity, and that it is converted to active pepsin in slightly acid solution. The progress of the activation is made possible by the initial formation of a trace of pepsin, which then starts the activation of the remaining pepsinogen—that is, the reaction is autocatalytic. This activation is accompanied by a splitting-off of nitrogenous compounds, so it is probable that the formation of the active enzyme from the inactive precursor involves rupture of some of the peptide linkages in the latter.

Thus, with the progress made in the isolation and crystallization of what is likely to be established as the enzyme proper, and with the elucidation of the processes of activation of inactive precursors, enzyme action will be reduced to the physics and chemistry of a special kind of catalysis. These enzyme proteins must possess peculiarly active groups or configurations, perhaps made available for action by the characteristic temperatures and *p*H requirements, which permit of the formation of combinations with the substrates so that rupture at certain points of the molecule of the latter occurs rapidly in an aqueous medium. Much of the old ground will, we imagine, have to be gone over, using crystalline enzyme proteins, before a reasonable hypothesis is forthcoming. The great advance so far has been that enzymes need be regarded no longer as mysterious agents working in a way which puts the chemist to shame, but as clear-cut chemical entities which are amenable to the methods of investigation already familiar to us but requiring a much more profound understanding of protein chemistry and physics than we yet possess.

SOCIAL FACTORS IN MEDICINE

The correspondence which has appeared in our columns under the title "Medicine in a Changing World" reveals some difference of opinion as to the functions of the medical profession in relation to the community it serves. There can, at least, be no doubt about our duty to find out if individual patients are so affected by their physical environment or by mental stress that their recovery from somatic disease is hindered; and to compile and broadcast such scientifically ascertained facts as indicate the extent to which the well-being of the people is adversely influenced by social circumstances. In the field of nutrition, for instance, it is our task both to keep our patients right and to make known to the whole community the physiological facts and their relation to economic and social circumstances without knowledge of which they cannot properly order their lives. It was the work of James Lind that enabled Captain Cook to make his famous voyages with an unprecedented freedom of his crews from scurvy, and Lind and John Pringle showed by their rules of hygiene for the navy and army how typhus could be controlled in any community. About the same time Percival, Ferriar, Currie, Haygarth, and Thackrah were piling up evidence of the deleterious effect on health of the evil state of the towns and factories. The medical observations of these men led to their open advocacy of reforms which were later effected through the political efforts of men like Shaftesbury and the administrative persistence of Chadwick and Simon, himself the first medical man to hold high public office. But perhaps no single individual had more influence on the character of the great public health movement of the nineteenth century than John Snow, who appears to have been less concerned with propaganda than with proving by scientific inquiry that cholera was a water-borne disease. Whatever may be the best attitude for the profession in these matters there can be no question that the effect of environment on health and recovery from disease is a subject of intimate concern to them and that it ought to be in the forefront of their minds from the very beginning of their student days. In some of the provincial schools, and especially in the Scottish universities, where there was intimate contact with civic life, the older clinicians who had lived and worked through the squalor and epidemics of the industrial revolution carried their experience to the classroom and the bedside. But when sanitation had solved its grosser problems and public health became a specialty, students, if they were taught preventive medicine at all, were often bored with disquisitions on the technique of a subject they foresaw no prospect of practising. In spite of lip-service to the unity of preventive and curative medicine the practice of hygiene has increasingly parted ways with the practice of clinical medicine.

That there is a close connexion between successful therapy and the domestic and occupational surroundings of patients has been recognized in hospitals by the establishment of almoners, whose business it is to gather the facts for the use of the clinician and to try to establish so far as possible the milieu which will favour the maximum restoration to full health and least exposure to relapse. The Americans have accepted more whole-heartedly than we have the idea of the social service department in a hospital, and, above all, its place in the teaching of medical students.[1] And yet Dr. Edward L. Bortz, physician in the Lankenau Hospital, Philadelphia, deplores the fact that still only eleven medical schools in the U.S.A. arrange for their social workers to participate in the training of medical students.[2] From a study of 200 patients suffering from cardiovascular, diabetic, gastro-intestinal, respiratory, nervous, and other conditions, he concludes that 75% were affected by social circumstances aggravating their medical state and impeding their recovery. These ranged from absence of economic security, bad physical surroundings, physical strain, and lack of assistance, which are of the same order as those defects which engrossed the minds of our forerunners, to marital or family conflicts, fear of dependancy from sickness, uncongenial employment, solitude, and personal inadequacy (which presumably

[1] *British Medical Journal*, 1936, 2, 563.
[2] *Ann. Intern. Med.*, 1940, 14, 1765.

means inability to adapt oneself to a way of living). The community, of course, makes local provision for dealing with some of these problems. Bortz, however, is convinced that in many cases education of the patient and his family by the doctor with the assistance of the social worker is essential for any lasting improvement, and he also advocates an intensive and widespread educational campaign to impress upon the laity, rich and poor in all walks of life, that sound health is very largely a matter of their own responsibility.

Some additional means have to be found of reaching those whose interest is enlivened by the presence in their homes of an immediate medical problem, not of a nature or at a stage within the scope of hospital treatment. Here is the realm of the general practitioner, who learns by experience and knowledge of the families under his care how they are affected by minor strains and sorrows of life as well as the slings and arrows of outrageous fortune. He comes to know for his own area where to direct them for assistance. But he has to find out most of this for himself in the hard school of practice. The medical schools of Great Britain, being centred on hospitals, make little contact possible between the student and the patient's environment, even if they have an almoner's department. The "clinical case studies" of the more progressive American schools, which take the student to the social service worker, to the home or the works, and even force him to examine the public health organization of his area, do not seem to have been adopted by any school in this country. The young graduate goes out into the world largely ignorant of the effect of circumstances which are as likely to affect 75% of domiciliary patients as of those in hospital. It is not enough, however, that this should be put right. Medical practitioners cannot deal fully with such matters single-handed. For one thing, inquiries and guidance of the kind needed are too time-consuming. Further, although many patients or their friends will tell some things most readily to their doctors, others speak more freely to a sympathetic woman with a non-medical training. The association of workers of this kind with the field of domiciliary medicine is one of the components to be considered in the post-war reconstruction of medical practice which is in all our minds.

AMERICAN DOCTORS FOR BRITAIN

In a written Parliamentary reply to Sir Henry Morris-Jones, Mr. Ernest Brown, the Minister of Health, outlining the recommendations of the Robinson Committee, referred to the recruitment of medical practitioners from the U.S.A. as a new factor in regard to which action should be taken as quickly as possible. There is every indication that the response on the part of American doctors to the appeal for service in this country is warm and spontaneous. These men will come over full of enthusiasm, and may expect to be thrown into the front line of the medical effort almost immediately on arrival. There can be no doubt at all that the help of these American doctors is needed, even with careful reorganization of our own medical personnel on the lines of the recommendations made by the Robinson Committee. Their services will be used chiefly in the R.A.M.C. Some will find employment in the Indian Medical Service and Colonial Medical Services. It is, however, important that they should have a clear idea of conditions here, and of the inevitable waiting periods that must occur at those times when the activity of the enemy slackens both in this country and in the theatres of war over-seas. It is a fact that many officers in the R.A.M.C. find time hanging heavy on their hands. And it is also a fact that this cannot always be avoided, because they have to be kept ready for action and no one can foretell when the action will come. It is also possible that doctors straight from active practice in clinical medicine do not readily adapt themselves to the task of maintaining the fitness of bodies of men who are mostly free from ailments, and do not realize that this is a field which ought to occupy their time profitably. Nevertheless complaints have been heard from doctors in the Army that scope is not given them for the full employment of their professional skill, and that much of their time is taken up with routine administrative duties. This may in part be due to the inflexibility of the Army machine and its reluctance to adapt itself to the peculiar conditions of the present war, when the brunt of the attack is being borne by the civilian population. But the conditions of military medical practice differ from those of civilian practice, and the temporary R.A.M.C. officer has to adapt himself to "a style of life" that is determined by many factors outside his control.

Although it is understandable that the civilian doctor turned officer does not take readily to administrative duties, the regular R.A.M.C. officer realizes the necessity for retaining these under his own control if efficiency is to be maintained. The burden of the complaint, however, is not so much that office duties interfere with professional work, but that in the average general-duty appointment there is not enough work to go round. For our part we should understand that American doctors come from a country different in traditions and outlook, although sharing a common tongue and a common heritage, and we cannot expect them to take for granted the peculiarities of the British temperament and the occasional obtuseness of the official mind. It is important, therefore, that they should have every opportunity for professional service and that consideration be given to the kind of work they wish to do and where they are to do it. Special staff officers should be appointed to look after their interests and to satisfy themselves that the best possible use is being made of their skill and knowledge. This may be done by frequent visits to stations where they are serving and by friendly unofficial conversations. If, by reason of an incomplete understanding of the situation, they come to feel that they are not being fully employed, the repercussions on their friends and colleagues in the U.S.A. might not be altogether favourable to us. It is to be hoped, therefore, that the quick action to which the Minister refers would be to give these colleagues of ours the fullest opportunity for "quick action" in the actual medical and surgical work they desire to perform.

IMMUNIZATION AGAINST TUBERCULOSIS

A somewhat neglected field of preventive medicine in this country is protection against tuberculosis by active immunization. This can only be considered necessary for restricted classes of individuals, among whom children in tuberculous families are the most important, and medical students and nurses may also be included. It has been amply demonstrated experimentally that some degree of resistance to infection can be produced either with a simple vaccine composed of killed tubercle bacilli, or by inoculation with living but avirulent organisms. The B.C.G. strain, a bovine tubercle bacillus the virulence of which has been reduced almost to *nil* by prolonged artificial cultivation, has been extensively used in France for this purpose, although with results which it is almost impossible to assess. Apart from attenuation in culture, another cause of reduced virulence not only in tubercle bacilli but among micro-organisms generally is origin from or habituation to another animal species. Those who remember the "turtle bacillus" vaccine will know that this possibility has not been altogether unexplored in tuberculosis; the cold-blooded type of tubercle bacillus is probably too distant a relation of the human or bovine to produce the necessary response. Evidently in quite a different category is the vole acid-fast bacillus discovered by A. Q. Wells. The position of this organism, which is the cause of an epidemic disease among wild voles, was at first uncertain, but it is now regarded as a distinct type of tubercle bacillus. Only large doses of 5 mg. or more cause progressive disease in guinea-pigs, and it was thus naturally of interest to inquire what effect sublethal inoculation with the vole bacillus has on subsequent infection with human or bovine bacilli. The first results of experiments on these lines by A. Q. Wells and W. S. Brooke[1] are very striking. Guinea-pigs were given four weekly injections of living vole bacilli, making a total dose of 2 mg., and inoculated with virulent human or bovine tubercle bacilli five months later. Another group of animals was treated in the same way with B.C.G., the total dose being 30 mg. Unfortunately the scale of the experiment was reduced by intercurrent disease, and it had to be terminated abruptly at the outbreak of war, all the animals consequently being killed eleven weeks after the infecting dose. The findings at this stage are nevertheless remarkable. Unvaccinated controls had extensive generalized tuberculosis; animals immunized with B.C.G. also had generalized infection, although in a less advanced stage; but of fifteen guinea-pigs immunized with the vole bacillus, seven of which were inoculated with virulent bacilli of human type and eight with bovine, two showed no lesions at all, nine had only a small abscess at the site of inoculation, and the remaining four had in addition small visceral tubercles. The degree of resistance produced by living vole bacilli—at least as indicated by the course of infection during the first three months—is therefore much greater than that attainable with B.C.G. These observations have been extended by A. S. Griffith and T. Dalling.[2] Using somewhat larger immunizing doses of vole bacilli, and a much larger subsequent inoculum of virulent bovine bacilli, they found only local or early generalized infection in guinea-pigs killed after ninety-four days, by which time all unvaccinated controls had died of tuberculosis. In another series of guinea-pigs the total survival period was determined; all the vaccinated animals died of tuberculosis in periods varying from 109 to 225 days, with an average of 152; for controls the figures are 67 to 111, average 87. These authors have also made similar observations in calves, vaccinating them with the vole bacillus by either subcutaneous or intravenous injection, and later administering virulent bovine bacilli by the mouth. Whereas unvaccinated controls developed extensive glandular tuberculosis, the vaccinated animals were found to have either no lesions at all, or only a few scattered foci in mesenteric glands. All these results are highly encouraging, and if more extensive experiments confirm them field trials in cattle on a large scale will be amply justified. It is reasonable to hope that the vole bacillus may be equally non-pathogenic and yet an effective immunizing agent in the human subject, but no direct evidence of this is yet forthcoming.

HYSTERICAL CONTRACTURE IN WAR

One outstanding medical achievement of the last war was Sir Arthur Hurst's discovery that the so-called "reflex paralysis," described by French neurologists as occurring in connexion with wounds without actual injury to the nerve, was not really reflex at all, but the result of hysterical perpetuation of a posture resulting from pain or spasm, or simply from splinting in a given position. The patient, so to say, does not realize when he has recovered, and maintains his posture and habit long after the need for it has departed. Sir Arthur Hurst showed not only that the limb can be restored to normal position and function by persuasion and explanation, but that the associated trophic changes can also be abolished by this means. It is important that at the present time this should be widely known, especially to surgeons and orthopaedists, so that reflex paralysis may not again appear in the catalogue of war disabilities. Observations on "reflex paralysis" show how it comes about that hysterical contractures of this type—that is, not primarily structural but volitional—can so often occur. Actually not volition but postural habit is involved, and no question of fatigue or of conscious co-operation need arise. This implies that the causes which Hurst described in the last war were psychologically of a simple kind and that the sufferers lacked positive motive for the continuance of their disability. If this were not so they would not have lost their disability so readily, or they would have replaced it by symptoms of another kind. The desire to escape from the Service or from some aspect of it could hardly have been present in individuals who were so readily cured without residual symptoms. It seems desirable to add this caveat so that doctors now treating such conditions may not be surprised if, while the war lasts, their efforts are less uniformly and immediately successful than those described in Hurst's classical paper.[1] The original work in fact, while recognizing psychological factors, ignored the possible existence of unconscious motives.

In a short restatement of his views recently published,[2] Sir Arthur Hurst gave some additional observations which are worth noting. The fact, for example, that the spasm of tetanus may be perpetuated hysterically is an exception to the rule that a hysterical paralysis is always such as can be imitated voluntarily with exactitude. Hysterical contractures described by him occurred frequently in normal men without any personal or family history of predisposition, whereas most war neuroses occurred in the martial misfits. Too little attention seems to have been paid in the last war to this matter of predisposition, which Hurst did not fail to note. Physiotherapists of all types would do well to notice his observation that they sometimes fail to enlist the active co-operation of the patient, who is too often allowed to lie back passively and

[1] *Brit. J. Surg.*, 1919, 6, 579.
[2] *Clin. J.*, 1941, 70, 29.

expect the apparatus or the masseur to do all the work. An interesting explanation is suggested for the alleged breaking down of adhesions in manipulated joints, whether these are disabled from functional or organic causes. What is heard may be the tearing of ligaments rendered brittle, so to speak, by circulatory stasis. If the stasis can be abolished first of all by encouraging the patient to move the joint, the sound of tearing is no longer heard.

ACUTE BILATERAL ADRENAL HAEMORRHAGE

A case of supposed malignant measles recently described in the *Journal* (March 8, p. 380) led a number of correspondents to point out that the facts were more consistent with a diagnosis of acute bilateral adrenal haemorrhage, the so-called Waterhouse-Friderichsen syndrome. This condition is probably more common in this country than is generally supposed. Some 70% of the published cases were associated with meningococcal infection, and during the present epidemic, or high endemic, meningococcal prevalence the proportion is likely to be nearer 100%. A recent comprehensive review by Lindsay *et al.*[1] adds four infections with meningococcus, two with *H. influenzae*, and one with *N. flavus* II to the ninety cases previously published. The haemorrhage in the adrenals was bilateral in 95% of the reported cases, but its degree varied from petechial haemorrhages to a large bleeding which converted the organ into a "blood cyst." In the milder degrees of haemorrhage the medulla was more involved than the cortex. All but one of the published cases were fatal and verified post mortem, but there seems to be no reason why some of the milder cases should not recover, as we can now combat the causal infection so much more effectively.

The syndrome has been chiefly found in infants and young children, 70% of the patients being under 2 years of age and only 10% being adults. The onset is that of a sudden fulminating infection. A previously healthy child vomits or wakes from sleep with a cry, is fretful, refuses food, and has a slight elevation of temperature and increased respiration rate. There may be some abdominal pain and diarrhoea, or even chills and convulsions. Physical signs at this stage are absent, but the child is obviously critically ill. In about half the cases cyanosis of lips and finger-nails occurs within a few hours of onset, and in all cases shock and collapse rapidly supervene. Within eight to twelve hours petechial and purpuric spots can be seen on the face, trunk, and limbs, and soon larger purpuric areas up to half an inch or more in diameter appear. Concurrently the patient generally lapses into stupor and coma. At this stage there may be slight neck rigidity, but more often there is muscular flaccidity. The spinal fluid is often clear, and the cell count averages 50 to 100 per c.mm. with a preponderance of polymorphs. The meningococcus or, rarely, other organisms (chiefly *Str. haemolyticus, H. influenzae, Staph. aureus*, or the pneumococcus) may be cultured from the spinal fluid or from the purpuric blotches. There is a polymorphonuclear leucocytosis. A low blood sugar is a valuable diagnostic sign when it occurs. The adrenal haemorrhage may happen at any stage after the appearance of the rash, generally within a few hours. The pulse then becomes weak, irregular, and of low tension, or it may be imperceptible. An attempt should be made to measure the blood pressure: complete absence of sounds strengthens the diagnosis. Too often there is little time to institute the therapy which is indicated. This consists of (1) intravenous sulphapyridine or sulphathiazole to combat the invading organism; (2) adrenal cortical extract or its equivalent in doses of 10 c.cm. or more twice daily—intravenously if possible—and perhaps adrenaline as well; (3) saline and glucose solution intravenously. Carey[2] reported a recovery in a female aged 27 years after treatment on these lines; until it has been tried out on many more cases it will be impossible to assess the value of adrenal and sodium therapy. G. E. Harris,[3] however, claimed three recoveries in meningococcal cases of the syndrome with imperceptible pulse on admission. Another recovery in an adult (unpublished) took place recently. In this case there was uncontrollable vomiting, muscular pains, a profuse generalized purpuric rash with some large patches, and a blood pressure that could not be recorded. All claims of recovery should be well documented in order that there may be no reasonable doubt of the diagnosis.

ATRIAL SEPTAL DEFECT

In the past, patent foramen ovale, which has no effect on cardiac function, has been confused with atrial septal defect, a truly congenital and important cardiac lesion. Until a few years ago it was rarely diagnosed in life, yet, according to D. E. Bedford, C. Papp, and J. Parkinson,[4] it is the commonest of all such lesions. Their account, which is based upon fifty-three cases, including ten necropsies, shows that most of the cases occur in females, and that death from heart failure is not usual before early adult life or middle age. The heart may be quite large and yet symptoms remain slight for a considerable time. Clubbing of the fingers and cyanosis are usually absent until a late stage, and murmurs, if present, are due not to the defect itself but to associated changes in other parts of the heart and vessels. The apex beat is often forcible and displaced to the left, and is then produced by the hypertrophied right, and not the left, ventricle. In the absence of hypertension, or a history of it, or of aortic valve lesions, this type of apex beat is a small clinical clue to the diagnosis. Mitral stenosis was present in a high proportion of the cases in addition to atrial septal defect, an association which has been noted by others, and in these auricular fibrillation may occur. But this arrhythmia may develop in the older patients with atrial septal defect alone, in contrast to other forms of congenital heart disease, in which fibrillation is almost unknown. Radiological examination reveals the characteristic changes, and on this a correct diagnosis largely depends. It shows the main and branch pulmonary arteries to be considerably enlarged, and in the latter pulsation may be conspicuous in the hilar regions. The left lower cardiac contour is prominent and is formed by the right ventricle; the left auricle is not enlarged and the lung fields not congested. The changes in the electrocardiograph are of greater diagnostic value than in most other forms of congenital heart lesion, the chief being right axis deviation, partial or complete right branch block, abnormal P waves, and prolonged P-R interval. The differential diagnosis is from other causes of moderate or great enlargement of the pulmonary artery. The implication of this interesting account is that atrial septal defect should be recognized more often. No doubt it will be when it is more widely appreciated that, as in some other forms of heart disease, the *x*-ray appearances alone can establish the diagnosis.

We regret to announce the death of Dr. George Lovell Gulland, emeritus professor of medicine in the University of Edinburgh and consulting physician to the Edinburgh Royal Infirmary.

WHITHER WELFARE?

BY

CICELY D. WILLIAMS, D.M., M.R.C.P., D.T.M. & H.

Lecturer in Paediatrics, College of Medicine, Singapore

"Society must measure its well-being in terms of the health of its children."—McCOLLUM.

"Medicine, when confining itself to the study of disease, amputates a part of its own body."—CARREL.

"Paediatric practice offers the widest and most fundamental opportunities for the prevention of disease."—ROLLESTON.

Twenty years ago there were many subjects that seemed to be well established and well developed, including Christianity, the classical virtues, and medicine. Within the last few years, and more particularly within the last few months, they appear to have become younger, less mature, more urgent.

One of the most serious problems we have to face is that of economics. Will all medical and social services be drastically reduced? Can we any longer afford our plethora of general hospitals, small, voluntary, special, municipal hospitals, homes, sanatoria, school clinics, treatment centres, crèches, nurseries, chemists' shops, doctors, nurses, masseuses, bone-setters, faith healers, patent medicines, patent foods—in fact all the paraphernalia that purveys health, from the most devoted and sincere to the most commercial and quackish? Will the war result in a serious curtailment of all the amenities of life, all the advantages of our civilization? Or will it precipitate the formation of a health service that will gain in efficiency what it loses in complications, redundancy, wasteful expenditure of time, energy, emotion, and vested interests?

It is essential for us to part with all our preconceived ideas, however painful the operation may be, and, by employing all the perspicacity and all the common sense we can command, to classify desirabilities in their most intelligent order.

The Function of Medicine

Time was when to cherish the poor, to alleviate suffering, to feed the hungry, was looked upon as a means of salvation for the righteous rather than as an obligation of the citizen and a duty of the State. The modern State realizes that the health and well-being of its citizens, whether they be rich or poor, are an important asset. In former days legislation was only concerned in protecting the health, the happiness, and the property of those who were not fortunate enough to possess these things. It is now realized that it is equally important to supply those who have not.

Medicine started out as the study of human ills. Medicine men among some peoples will obligingly attempt to treat illness, direct emotions, and control the weather. It is unfortunate that for a time so-called scientific medicine has forgotten some of its concerns. It has almost ignored the things that could not be weighed, measured, or observed with an oil-immersion. It is only of recent years that such words as "environmental hygiene" have been invested with any seriousness. But disease means lack of ease. It does not imply bacterial, toxic, traumatic, mental, spiritual, nutritional, or domestic maladjustment. But it may mean any or all of these. The patient is not merely the embarrassing by-product of some pathological state. His self-respect and ambition must be fostered before he can even imagine his own possibilities.

To observe all the factors that affect human welfare needs good medical training as well as common sense. Sometimes it appears that medicine only begins where common sense ends.

On one occasion a doctor was summoned to the radiological department. The radiologist turned over pages of notes. "What do you want this barium meal for?" he asked. "Here is a poor old lady of 60. She has already had a blood count, a W.R., complete urine and faecal analysis, fractional test meal, etc. If you find an organic lesion she will only refuse operation, and, anyhow, she probably isn't fit for it. What good do you expect to do?" "Good?" replied the doctor. "Good? I don't expect to do any good. This is art for art's sake. If I ask for health visitors to follow up my cases, if I ask for opportunities to teach mothers how to look after their children, if I suggest that it might be easier for health visitors to prevent disease if they came here and learned something about the diseases they are trying to prevent, then I am told that I am interfering in matters that do not concern the hospital or myself. But I am required to spend a large portion of my time on work that is not in the least likely to do any good. Patients are asking for bread and we give them a barium enema. They used to call medicine the healing art. It seems to get more and more art and less and less healing."

The Present

We always seem to tackle human welfare from the wrong end. We set up medical schools and train doctors long before we have studied local conditions and local needs. We prefer to force diseases into categories rather than to study their aetiologies. In medical colleges much of the teaching is done by men who for years have had no contact with the conditions of living of the patients on whom they do the teaching. "Doctor," instead of meaning "teacher," generally means a bottle of medicine. When a medical student sees a child with dyspnoea he invariably suggests intranasal oxygen before he thinks of cleaning the nose.

Specialists have been so dazzled by advances in chemistry and mechanics, health officers have been so absorbed in bacteriology and in plumbing, that it has largely been left to the non-medical members of the population to realize the importance of domestic details in the cure and in the prevention of disease. Florence Nightingale was quite right. She sometimes deplored the discoveries of Pasteur and the development of bacteriology and immunology. They would, she said, absorb attention which should more profitably be spent on the benefits of good food, cleanliness, and fresh air.

Even the more modern developments of medicine—the health departments—have misconstrued the word "epidemiology." Many health officers have a sort of Black Death mind. To them the only sort of disease is a notifiable disease. If a town is free from plague, cholera, and small-pox they call it "healthy" or "remarkably healthy," although the infant mortality stands at 150. When the major epidemics have been reduced and a couple of decades have been spent in self-congratulation, the health officer then turns his attention to tuberculosis, venereal disease, and maternity and child welfare. His clinical work has never included much of these subjects. What it did he has forgotten. But he is undismayed. He and his staff set out to prevent disease. Then one sees the woman with a nutritional dermatitis being treated as a syphilitic and the child with beriberi being treated for tuberculosis, all because we insist on thinking in terms of specialisms and of diseases rather than in terms of patients.

"Tropical Medicine" is a label that has misled a great deal of observation and of thought. If we had given more time and attention to the oecology of disease instead of to its biochemistry, to its external implications instead of to its internal, we should have learned a great deal more about it.

Great discoveries are made and heralded with applause, but how many of these discoveries are implemented so as to contribute to human welfare? Everywhere the feeling is growing that the amount of time, money, and energy spent on research work is disproportionately great compared with that spent in making discoveries available *and acceptable* to masses of dirty, diseased, ill-fed, and unhappy people. Why are lunacy and carcinoma of the cervix both exceedingly rare in the West African female? Why is mental hygiene almost ignored? Why are white bread and polished rice still eaten in large quantities? Why the profound sartorial gulf between the honorary staff and the M.O.H.?
